Comparison of Thiouracil and Propylthiouracil.—A statistical comparison of 98 thyrotoxic patients treated with 0.6 Gm. of thiouracil per day and 42 treated with 0 15 Gm of propylthiouracil per day revealed practically identical effectiveness of the two drugs in these doses The incidence of toxic reactions with propylthiouracil is much less than with thiouracil Severe toxic reactions might be encountered if the present dosage of propylthiouracil is significantly increased The available data indicate that 150 mg is probably the most satisfactory maximum dosage of propylthiouracil

Infectious Hepatitis in Childhood —Horstmann and her associates describe two epidemics of infectious hepatitis in children In one, 53 cases of hepatitis with jaundice occurred along with 56 cases of questionable hepatitis without icterus In the other institution 68 patients developed hepatitis with jaundice, of these 44 were children In all of the juvenile patients the disease was mild and of relatively short duration as compared with the disease in adults The difference between the severity of infectious hepatitis in children and in adults is comparable to the difference which exists between the childhood and adult forms of the more common virus infections Measles mumps and chickenpox are all likely to be more severe and attended with more severe complications in the adult than in the child The authors deplore that the mildness of infectious hepatitis in children has tended to cause the disease to be belittled There is no evidence that such mild cases are less dangerous to the community from the infectious point of view than are the more severe adult cases

Hypercalcemia and Hyperplasia of Parathyroid in Infant —Pratt and his associates present clinical and laboratory investigations on an infant aged 10 months exhibiting extreme hypercalcemia mild acidosis impairment of renal functions and low urinary excretion of calcium The postmortem examination revealed chief cell hyperplasia of all four parathyroid glands, nephrocalcinosis and osteitis fibrosa The apparently unique combination of hypercalcemia and chief cell hyperplasia of the parathyroids was not satisfactorily explained

Parenteral Administration of Vitamin D —Vollmer and his co workers describe experiments on rats which were carried out to determine the comparative therapeutic and prophylactic effect of a single massive dose of vitamin D_2 administered orally in oil, intramuscularly in oil and intramuscularly in oil-ether solution The superiority of the oil ether injection and the oil injection over the oral doses was statistically significant The superiority of the parenteral vitamin D administration in an oil ether vehicle in the therapeutic as well as the prophylactic experiments seems to indicate quick absorption and satisfactory retention of the vitamin administered by this method The inferiority of the parenteral administration of vitamin D_2 in oil in the therapeutic experiments may be ascribed to a delayed vitamin D absorption from the oily deposit in the tissues The inferiority of the oral administration of vitamin D_2 in oil in the prophylactic experiments may be explained by incomplete absorption of massive doses from the gastrointestinal tract and loss of vitamin D with the feces If observations in animals are applicable to infants and children, one may expect that intramuscular injection of a single massive dose of vitamin D_2 in an oil-ether vehicle will cure rickets at least as promptly as other methods of administration and is at least equivalent to the other methods in its prophylactic effect, giving complete protection against rickets for at least three months

Treatment of Hyperthyroidism.—Crile thinks that the disappointment felt by the profession in thiouracil and thiobarbital has prejudiced many physicians against the antithyroid drugs and has led them to regard with suspicion the more recently developed thiouracil derivatives This suspicion is poorly founded because propylthiouracil has proved safe and effective It accomplishes a physiologic rather than an anatomic thyroidectomy, and the mechanism by which it produces a remission is comparable in many respects to that of thyroidectomy Propylthiouracil is the treatment of choice for diffuse goiter with hyperthyroidism Thyroidectomy is seldom indicated Because adenomatous goiters are tumors of the thyroid and because tumors are potentially dangerous thyroidectomy is still the treatment of choice for most nodular goiters of significant size The majority of patients with nodular goiters and mild hyperthyroidism are best prepared for operation with iodine Propylthiouracil is used in the preoperative preparation of patients with severe hyperthyroidism of patients over 50 and of patients with complications increasing the risk of operation Nodular goiter with hyperthyroidism occurring in aging patients or in patients with short life expectancy can be successfully and definitively treated with propylthiouracil

Congenital Defects Following Maternal Varicella —Laforet and Lynch report that in an infant whose mother had varicella during the eighth week of pregnancy the following multiple congenital defects were present talipes equinovarus on the right side, paralysis and muscular atrophy of the right lower extremity, defective development of the toes of the right foot, cortical atrophy, hypoplasia or aplasia of the cerebellum, bilateral optic atrophy, pilonidal sinus, torticollis to the right, cicatricial lesions of the skin of the left lower extremity, undescended testis on the left and insufficiency of the anal and vesical sphincters. The episode of maternal varicella was well authenticated. Reviewing the present opinion on the pathogenesis of anomalies associated with maternal antepartum virus infection, the authors emphasize the possible teratogenic propensities of maternal virus diseases occurring early in pregnancy.

Ligation of Vena Cava.—Collins and his associates say that ligation of the inferior vena cava and the ovarian veins has been done in 22 cases at Tulane University School of Medicine. They stress that ligation of the vena cava carries a low operative mortality. The end results and the appearance and function of the patients' extremities are good. The procedure is indicated in cases of phlebothrombosis of the iliac vessels whether the clotting process occurs preoperatively or postoperatively. It is also indicated in cases of postabortal and postpartal puerperal sepsis if conservative therapy is ineffective, if infarction to the lung develops or if the patient has an infarct to the lung from a suppurative pelvic thrombophlebitis when first seen. The minimal amount of edema and circulatory disturbance occasioned by vena cava ligation in the reviewed cases is due to the fact that at the time of operation the sympathetic chains are sectioned; if this is not possible at operation routine blocking of the lumbar sympathetics is performed, bilaterally, daily, for five or six days after operation.

Office Procedure for Penicillin Therapy of Suppurative Bartholinitis.—Goldberger and Lapid aspirate the suppurating Bartholin abscess and inject penicillin directly into the cavity. Three patients so treated all complained of an exquisitely tender local vulvar mass, extreme difficulty in walking and sitting and generalized discomfort. They all experienced immediate relief. One of the 3 patients had to be reaspirated twenty-four hours after the initial procedure because of the reaccumulation of pus in the cavity; this patient received 100,000 units of penicillin. The other 2 patients received 200,000 units of penicillin in one injection. With this procedure patients are not subjected to a minor operative procedure of incision and drainage with its postoperative care and longer reparative process. Within forty-eight hours there is no evidence of an inflammatory process.

Pyribenzamine in Treatment of Hay Fever.—Leibowitz and his associates review observations on the use of pyribenzamine hydrochloride in patients with hay fever due to ragweed. Of 86 patients 21 were treated with pyribenzamine alone, 47 with desensitization and pyribenzamine, and 18 with ragweed desensitization alone. The majority of patients obtaining relief from pyribenzamine, either alone or in conjunction with ragweed desensitization, required only two tablets a day. Side reactions occurred in 25 of the 68 patients receiving pyribenzamine. These effects disappeared gradually while the drug was still being administered. Pyribenzamine did not affect the blood count. The highest percentage of relief was obtained when pyribenzamine was administered together with ragweed desensitization (35 of 47). Pyribenzamine alone produced relief in 9 out of 21 cases. Ragweed desensitization alone relieved 10 out of 18 cases.

Hemolytic Anemia.—Herndon and Alexander studied the family of a woman aged 39 with congenital hemolytic anemia. Determinations of the hemoglobin red cell count, erythrocyte fragility tests and wet smear examinations for spherocytes were performed on 15 relatives in four generations. Six of these relatives presented definite laboratory evidence of defective erythrocytes, only 1 of them gave a history of jaundice, and the remaining 5 were reported to be in good health. Determinations were made of the blood groups, blood types and Rh factor in 16 members of the family and of the taste reaction to phenyl-thio-carbamide in 12 members of the family. Although this series is too small to be of significance in linkage calculations, the data are presented in the hope that additional similar data may become available. It is suggested that congenital hemolytic anemia is due to the action of a simple dominant gene, with variable expressivity. Emphasis is put on the fact that history alone is entirely unreliable in classifying relatives of a patient with congenital hemolytic anemia as normal or affected. The variability in the clinical picture is so great that accurate hematologic examination is necessary for proper classification of even apparently normal relatives.

BAL in Heavy Metal Poisoning.—According to Welfare there is evidence that arsenic produces intoxication in man and animals by depressing intracellular tissue respiration. It produces this depression by attaching itself to sulfhydryl radicals of enzymes responsible for the metabolism of fats and carbohydrates, thus interfering with the function of these enzyme systems. British Anti-Lewisite (BAL), a dithiol (2,3-dimercaptopropanol), by supplying more readily available sulfhydryl groups, is able to remove arsenic from the enzyme systems and thereby reactivate tissue respiration. BAL is a potent antidote for poisoning by other heavy metals such as mercury producing toxic effects in a manner similar to that of arsenic, and BAL is probably useful in the treatment of poisoning by bismuth, gold and antimony. On the basis of animal experiments it would appear that BAL is contraindicated in cases of poisoning by lead, thallium and selenium. While best results in heavy metal poisoning are obtained by early treatment with BAL, the compound was also effective when treatment was started three weeks after the appearance of erythema with a scaling eczematoid process and edema in a pregnant woman aged 39 with syphilis to whom mapharsen had been given; complete recovery resulted from the administration of a total dose of 3,750 mg. of BAL.

Psychologic Invalidism in Thyroidectomized Patients.—Ruesch and his associates review the results of personality study on 43 patients who had been subjected to subtotal thyroidectomy and were selected from the material of the thyroid clinic of the University of California Hospital in such a manner as to constitute a fair representation of the several thousand patients followed in the clinic The authors believe that patients who are afflicted with thyroid disease are not entirely normal as far as sociopsychologic aspects are concerned The group divides into two distinct entities the normal or almost normal girl and the hysterical or anxiety type While surgical procedures are tolerated exceedingly well by the normal girls, delayed recovery is almost a probability in anxiety types and hysterical characters In men the problem is similar, but instead of hysterical personalities one deals with dependent individuals In preparation for surgery, psychiatric interviews might be helpful in spotting personality deviations of the anxiety, hysterical or dependent type Therapeutic interviews before and after operation might improve the chances of recovery of patients with personality disorders

Phantom Limb—The report presented by Ewalt and his associates is based on observations on amputees during their stay in an army general hospital Of a series of 2,284 patients with amputations, 404 had detailed psychiatric study Phantom sensation has been found to occur in practically all individuals who are studied carefully Spontaneous complaints of pain were rather rare among the group The patients complaining of phantom pain were persons who had psychopathologic manifestations complicating the orthopedic picture The authors gained the impression that phantom pain is merely the interpretation of a phantom sensation by certain psychopathologic persons Two cases are reported which support this view In both the pain tended to come and go with psychopathologic symptoms irrespective of what type of external treatment was carried on

Roentgen Therapy in Hodgkin's Disease—Merner and Stenstrom review observations on 185 patients in whom Hodgkin's disease had been proved by biopsy Multiple areas are involved by Hodgkin's disease throughout the body, but the peripheral lymph nodes are most frequently affected, followed by mediastinal nodes, abdominal nodes, spleen and bones The disease is most common in the third decade, and about two thirds of the patients are males The authors believe that the method of irradiation developed at the University of Minnesota Hospitals is highly efficient in the treatment of the lymphoblastomas Treatment is considerably more intensive than in most series reported A full course of therapy is applied to each area of involvement the dosage varying between 1,000 and 2,000 tissue roentgens over a period of fourteen days Large masses are treated more intensively, and the group of enlarged nodes causing the greatest distress is treated first The five year survival rate was 21 per cent and the ten year rate 8 per cent Other statistics have also been presented, demonstrating the increase in the survival period from the onset of symptoms in treated cases as compared with a series of untreated cases of lymphoblastoma reported by Minot in 1926 The unpredictable nature of Hodgkin's disease is recognized and claims of cure cannot be made Roentgen therapy has greatly increased the survival rate

Penicillin in Nasal Infections.—Dunn presents an account of an attempt to treat infective conditions of the nose and accessory sinuses with penicillin. The selection of cases depended on the presence of a penicillin sensitive organism in the antral washes or nasal discharge, while the methods of administration were determined by the most efficacious means of delivering penicillin to the regions involved. Administration was local, intramuscular or oral or a combination of these methods. The majority of patients treated with penicillin claimed relief from symptoms and showed improvement on x-ray examination. The greater proportion of these would have responded to ordinary conservative treatment. Three patients from whose antral washes a pure penicillin sensitive organism was grown before treatment grew a culture of Bacillus pyocyaneus after prolonged penicillin treatment. Three patients developed a rash in the vicinity of the nasal vestibule, which cleared after the cessation of penicillin treatment. Penicillin counteracted secondary infection of the nasal passages following a common cold. In sinusitis only x-ray investigation can decide which method of applying penicillin would be most efficacious. Penicillin, helpful in the treatment of acute and subacute exacerbations, cannot produce permanent relief in the presence of gross chronic infective mucosal changes; nor can patients with antro-oral fistula, foreign body in the antrum or conditions producing stasis in the nasal passages or accessory sinuses hope for freedom from recurrence of infection if penicillin treatment alone is undertaken.

Massive Doses of Penicillin in General Practice.—Wheatley cites histories of 7 patients with conditions commonly encountered in general practice who responded well to large daily doses of penicillin. The first patient was a woman who had been troubled for some time with recurrent and severe boils in the nose. The usual duration of one of these was one to two weeks. When she consulted the author she had a full blown and painful boil just inside her nose. She was given 200,000 units of penicillin by intramuscular injection, this being repeated the following day. The next day the boil had almost completely subsided. The other patients had whitlow, carbuncles or purulent conjunctivitis. Carbuncles cleared up in about five days and the patients were fit for work within a week. In none of the patients was local treatment given after penicillin therapy was started. The 1 patient who was given penicillin twice daily fared no better than the others who received only one daily dose.

Vitamin A in Infective Hepatitis.—In preliminary experiments defective dark adaptation was used as an indication of vitamin A abnormality. Chemical methods were used in investigation made on 32 military patients, of whom 30 had infective hepatitis and 2 jaundice following arsenotherapy. Harris and Moore stress that in the early stages of infective hepatitis the vitamin A content of the plasmas was often low. In estimations by the antimony trichloride method, values of 30 international units per hundred cubic centimeters or less were sometimes observed, as compared with an average of 118 international units for normal subjects. The low plasma vitamin A seems an adequate cause of the impairment of dark adaptation in this disease. The plasma vitamin A increased during convalescence. Variations in the carotenoid content of the plasma were similar to those found for vitamin A, but the return to normal was less rapid. The changes in plasma vitamin A and carotenoids went roughly parallel with the prothrombin value and with hippuric acid tolerance and moved in an opposite direction to the plasma bilirubin. In "absorption tests" with massive doses of vitamin A it was found that in the early stages of infective hepatitis substantial amounts of vitamin A were excreted in the feces, and sometimes there were traces in the urine. Excretion was not found in normal subjects given the same doses or in the same patients during convalescence. In some cases the plasma vitamin A failed to show the usual rapid increase after massive dosing. It appears that in infective hepatitis the mechanisms responsible for the absorption of vitamin A from the intestine, for its deposition in the liver, and for its release into the blood stream are not always involved to the same degree. The interpretation of the results of "absorption tests" as a measure of the degree of injury to the liver therefore seems uncertain.

*Dermatitis as a Monosymptomatic Manifestation of Nicotinic Acid Deficiency. A. J. S. McFadzean.—p. 103.
Tomography of Bronchiectasis by Means of Preselected Planes of Section. E. Tiscenco.—p. 116.

Dermatitis and Nicotinic Acid Deficiency.—McFadzean directs attention to skin lesions attributable to nicotinic acid deficiency unassociated with other symptoms of such deficiency and occurring in otherwise normal persons. The lesions were seen in early summer in the Middle East in 62 men of European stock. The 44 cases making up the first group occurred in a closed community of 2,764 men on the same diet and living under identical conditions. Group 2 consists of cases seen in the wards or outpatient department of a Middle East general hospital. All stages in development of the characteristic skin lesions of pellagra were seen, varying from the acute erythema with edema, vesiculation and crusting to the classic hyperpigmented, hyperkeratotic plaques with desquamation. Clinically the skin lesions were consistent with the dermatitis of pellagra, and consideration of the distribution of the lesions and the relevant circumstances led to the hypothesis that they had been provoked by solar irritation These lesions could be reproduced experimentally by exposure to sun or to ultraviolet radiation and could be prevented or cured by large doses of nicotinic acid. Observations suggested that the local manifestations of nicotinic acid deficiency depended on local irritation; in the absence of this, no lesion developed A method of provoking dermatitis by ultraviolet radiation has been described and should prove of diagnostic value in subclinical or suspected nicotinic acid deficiency.

Systemic Torula Infection with Tumor in Meninges.—According to Krainer and his associates, typical cases of torula meningoencephalitis show diffuse, patchy meningitis with perivascular and embolic extension into the brain substance, while tumor formation in the meninges is rare and systemic lesions are usually inconspicuous The causative organism is a spheroidal, encapsulated, yeastlike fungus The case described in this paper concerned a Sikh, aged 32 It showed features distinct from the common clinical and pathologic picture of torula infection Systemic lesions were prominent before signs of central nervous system involvement The lesion in the cranium gave rise to the clinical picture of a space occupying lesion situated in the left frontal region At operation a globular tumor was found sharply demarcated from the brain substance and attached to the dura mater, the consistency and color being that of a meningioma. The microscopic examination showed the typical picture of torula granuloma Specific cerebrospinal fluid changes were absent before and after operation The causative organism was isolated from the systemic lesion of the right thigh before there were signs of a cerebral tumor. The organism was classified as type III of Torula histolytica Freeman

*Chang Shan in Treatment of Malaria Cheng Fang Tsu —p 75

Chang Shan in Malaria.—According to Cheng Fang Tsu, the indigenous Chinese drug chang shan has been used in China for the treatment of malaria for more than two thousand years. The vomiting produced by the extract prepared according to the old methods has been largely eliminated by a newer method of extraction The extract was given to 322 patients with benign tertian malaria; 67 per cent of these were cured, and of 253 patients with malignant tertian malaria 63 per cent were cured. A further series of 67 patients with tertian and 14 with malignant malaria were hospitalized and treated with chang shan. In most cases the chang shan extract was given by mouth, but in a few cases intramuscular injection was tried. The local reaction was not unduly severe. Gastric symptoms could be avoided by preliminary administration of bismuth subnitrate or hyoscyamus and sodium bicarbonate. So far no other secondary effects have been observed even when the individual dosage was raised to 8 cc. and the daily dosage to 40 cc.

*Toxic Effects of Thiourea, Thiouracil, Methyl Thiouracil and Aminothiazole in Thyrotoxicosis. Margaret E. Morgans —p 519.

Folic Acid in Sprue.—Davidson and his associates report the hematologic changes in 10 cases of the sprue syndrome after treatment with synthetic folic acid The hematologic response was considered unsatisfactory in 9 patients in that the treatment either produced no significant rise in the red cell count or failed to restore the blood level and hematologic picture to normal · Diarrhea was controlled and clinical improvement resulted in the 7 adults with tropical sprue or idiopathic steatorrhea. In contrast, no significant benefit was observed in the 3 patients with celiac disease. Folic acid did not improve fat absorption, as estimated by fat balance tests, in 5 out of 6 cases of the sprue syndrome. The unsatisfactory hematologic responses were in striking contrast to the results obtained by Spies et al and García Lopez et al. in cases of tropical sprue. These workers laid down criteria for the selection of patients, one of which was that the marrow should be megaloblastic. Only 1 of the patients in the authors' group had megaloblastic marrow at the start of folic acid therapy, and it was this 1 patient who obtained the most dramatic initial hematologic response.

Toxic Effects of Thiourea, Thiouracil, Methyl Thiouracil and Aminothiazole in Thyrotoxicosis.—Morgans found that thiourea and aminothiazole have many toxic effects and both depress the granular cells of the blood Their use in clinical practice is no longer justifiable. Thiouracil and methyl thiouracil also depress the granular cells of the blood, but during their use the incidence of other complications is much lower than with the other two drugs. Thiouracil and methyl thiouracil can be used with a reasonable degree of safety, provided the patients are carefully watched

Survival of Variola Virus in Dried Exudate and Crusts from Smallpox Patients.—Downie and Dumbell used chorioallantoic membranes of developing hen's eggs to detect the presence of virus in vesicle fluid and crusts from smallpox patients By this means virus was found to survive in diluted vesicle fluid dried on glass slides for thirty-five days when exposed to daylight and for eighty-four days when kept in the dark at room temperature Virus was recovered from different samples of crusts kept at room temperature for several months and from one specimen kept thus for over a year The authors have isolated virus from the sweepings from the ward floor near a bed in which a child was convalescing from smallpox. They also cite outbreaks among laundry workers who handled bedclothes of smallpox patients

Peripheral Venous Thrombosis: Preventive Measures and Treatment. A. B. Jones.—p. 297.
Postoperative Thrombosis and Blood Coagulation Times. H. Cummine. —p. 302.

Penicillin for Discharge from Middle Ear.—The records of the cases of discharging ears reviewed by Dunn were collected at the 115th (Heidelberg) Military Hospital. Penicillin was applied locally by intramuscular injection and by intramuscular and intrathecal injection. The response of a discharging middle ear to the local application of penicillin occurred within three to four days, while with intramuscular injections of penicillin about five or six days were required for the production of a dry ear. Forty of 63 patients with a middle ear discharge were found to be harboring a penicillin sensitive organism. Thirty of the 40 patients with a discharge from the middle ear which yielded penicillin sensitive organisms on culture responded to penicillin treatment. The intramuscular injection of penicillin was found beneficial in (1) acute otitis media: (*a*) patients not responding satisfactorily to sulfamerazine by mouth, harboring a staphylococcus in their aural discharge and obviously suffering from mastoiditis; (*b*) patients unable to be treated with sulfamerazine; (2) aural discharge following a fracture of the skull. In intracranial complications of mastoiditis penicillin therapy was disappointing.

Physiologic Basis of Modern Anesthesia. R. H. Orton.—p. 332.

Sulfonamides in Rheumatoid and Infective Arthritis.—Parr and Shipton experimented over a period of approximately nine years with small daily doses of the sulfonamides given for a long period with a view to ascertaining their effects in the so-called rheumatic diseases. A small dosage of three tablets per day (1.5 Gm.) was employed. In acute cases associated with fever, larger doses up to three or four Gm. per day may be employed. Of the complications the rash is highly irritable and possibly allergic in nature, but the changes in the hemopoietic system are the most important. The importance and significance of anemia, leukopenia and eosinophilia are stressed. Administration of liver and yeast are indicated to prevent their occurrence. The probable value of pyridoxine and folic acid is mentioned. The beneficial effect of the drugs is shown by the improvement in color, the disappearance of cyanosis, the relief or disappearance of pain, swelling and stiffness of the joints, an increase in the number of red blood cells and the improvement in the blood sedimentation rate. For patients who only partly respond to the sulfonamides, the authors recommend supplementary therapy such as liver extract, yeast, calcium gluconate, iron and perhaps gold therapy. The mode of action of the sulfonamides is discussed with regard to their interference with oxygen consumption, and the view is expressed that with the smaller doses there occurs a vital suppression of bacterial oxygen consumption and therefore of bacterial growth, enabling the body cells with their smaller metabolic demand to regain the mastery over infection. The importance of repeated blood counts is stressed.

Anesthesia for Upper Abdominal Surgery. I. A. Schalit.—p. 367.
Precautionary Measure Advisable in Certain Endurance Tests. W. J. Lawrence—p. 370.

Beneficial Effects of Yeast in Diabetes Mellitus.—Parr and Shipton give the histories of 4 patients who were treated with yeast. There was evidence of considerable recovery in some of the beta cells of the islands of Langerhans. One patient responded to treatment without insulin. Of the 3 patients receiving insulin, 1 experienced a 40 per cent recovery and another has been off insulin for about eighteen months. The third is showing a pronounced decrease in the blood sugar level and diminution of insulin requirements. Either brewers' or bakers' yeast can be used. The authors mention the ability of yeasts to control ketosis and make the suggestion that the increase of diabetes in civilized communities may be due to the lack of the vitamin B complex in food. The need of a better type of bread is stressed.

Fainting and Shock. J. W. Tomb.—p. 131.

Visceral Zoster.—According to Porteous painful visceral disease, not directly involving dorsal nerve roots, is sometimes associated with zoster in corresponding or neighboring dermatomes. The skin lesions may precede, accompany or follow the onset of visceral symptoms. A man aged 66, who for many years had been subject to nausea and heartburn after dietary indiscretions, for some months had noticed occasional soreness deeply situated beneath the left rib margin lateral to the rectus muscle. Two weeks before admission he experienced severe, shooting, knifelike pains in the right shoulder and back of the right arm, and four days later a zoster eruption appeared in the distribution of the tenth left dorsal nerve. The significance of the occasional pains beneath the left ribs, which were noted for some months prior to admission, is uncertain. Possibly they indicate that gastric ulceration was already present. Vomiting and gastrointestinal hemorrhage began five days after the appearance of zoster, and thirteen days later there was another severe hemorrhage, with probable perforation of the stomach and localized peritonitis. The pain felt in the right arm at the onset indicates that cervical as well as thoracic segments were affected by the herpetic process, and this is evidence in favor of the view that this was a case of "primary" or "idiopathic" herpes zoster with resulting visceral lesions. Complete recovery occurred.

Osteomalacia with Looser's Nodes (Milkman's Syndrome) Due to Raised Resistance to Vitamin D Acquired About the Age of 15 Years. R. A. McCance.—p. 33.

Hunger Edema.—Denz reports investigations on the plasma protein levels in a small number of cases of edema occurring among German civilian internees. Total plasma proteins are decreased in patients with edema. Mean values of 5.24 Gm. per hundred cubic centimeters of plasma in slight cases, 5.07 in moderate cases and 4.90 in severe cases were obtained as compared with 7.04 Gm. for a normal control group. Plasma-albumin values in 14 edema cases ranged from 2.58 to 3.81 Gm. The lowered plasma proteins are believed to result in the accumulation of edema that commences with the first lowering of the protein level. The view that there is a critical level of plasma protein for the production of edema is not accepted. Four patients with apparently cured edema were exercised with reappearance of the edema. Two patients with edema were exercised while on full diet with persistence of the edema until the patients were allowed complete rest. Daily plasma protein determinations on edema cases showed a diurnal variation which was probably due to variation in the degree of hydration of the blood. The inaccuracy of the clinical assessment of edema is illustrated by a patient showing minimal edema, who lost

8 5 liters of edema fluid whereas another showing severe edema lost only 2 liters of edema fluid Much excess fluid may be hidden in the deeper connective tissues of the mediastinum and abdomen

Edematous Syndrome of Nephritis—Remme discusses the fate of patients with that form of Bright's disease characterized by persistent edema and heavy proteinuria The authors review the course of the edematous syndrome in 29 patients and determine the functional state of the kidneys in the survivors The observations extended over a period of sixteen years None of the patients had a history of acute nephritis In 1946, 13 patients were alive Three appeared to be well in every respect seven, thirteen and fifteen years from the appearance of edema and 2 six and fourteen years afterward showed a faint trace of albumin in the urine as the sole abnormality Three patients, although free of edema showed greater albuminuria and microscopic hematuria Of the remaining 5 3 were still edematous and 2 although free of edema, were showing increasing hypertension Sixteen patients had died 12 of uremia, 3 of intercurrent infection and 1 after an intravenous injection of a mercurial diuretic All three recoveries were noted in patients in whom hypertension azotemia and hematuria were not observed Hypertension was an early indication of a progressive lesion Of 14 patients with hypertension when first seen 8 died of uremia and only 1 of the remainder improved

Injury of Ampulla of Vater in Gastroduodenectomy—The possibility of injuring the choledochus and Wirsung's duct in the course of gastroduodenectomy is one of the arguments often and justly invoked in opposing exeresis of chronic ulcers that have deeply penetrated into the pancreas Santy and Duroux show that this is a comparatively rare occurrence and that this risk can be accepted, because means are available to remedy it

Procaine Infiltration of Carotid Sinus—Creyssel and his associates point out that since 1940, when they reported their first experiences with procaine infiltration of the carotid sinus for traumatic shock, this therapeutic method has been repeatedly discussed in the literature Infiltration of the carotid sinus has been employed in five groups of cases: traumatic shock, surgical shock, obstetric shock, collapse due to acute peritoneal syndromes and adrenal insufficiency Experimental studies have not only demonstrated the prophylactic value of carotid infiltration against operative shock but have also thrown light on the physiologic action of the sinus The authors list indications for its employment and suggestions with regard to conditions in which it might be employed, such as grave craniocerebral trauma, epileptic attacks, cerebral apoplexy, laryngeal spasms and syndromes of parathyroid insufficiency

*Jaksch-Hayem-Luzet's Anemia. G. Careddu.—p. 721.

Jaksch-Hayem-Luzet's Anemia.—Careddu reports the occurrence in 2 infants aged 20 and 16 months, respectively, of Jaksch-Hayem-Luzet's splenic anemia which became manifest in early infancy and appeared to be caused by chronic suppuration of the scalp. Syphilis, tuberculosis, leishmaniasis and malaria were ruled out. Brothers and parents were normal. The differential diagnosis between this type of splenic anemia and Cooley's and Di Guglielmo's form is facilitated by the difference in fragility and the size of the erythrocytes. Jaksch-Hayem-Luzet's anemia is rare. The 2 reported cases were seen in a group of 50 cases of anemia in children.

*Diphtheria in Uruguay. C. Fabini and A. Panizza Blanco.—p. 221.
Technic for Determination of Blood Group of Hemolyzed Blood. H. Mazzella.—p. 268.

Diphtheria in Uruguay.—A review of the epidemiology of diphtheria in Uruguay before and after the establishment of obligatory vaccination of school children shows that morbidity and mortality indexes from diphtheria have greatly diminished in children in the age group 6 to 14 years, have moderately diminished in infants and children in the preschool age as a result of vaccination (although it is not as yet obligatory for children in this age group) and have not changed in infants in the first six months of life and in adults (age groups of nonvaccinated persons). At present acute diphtheria occurs in children who have had no vaccination and in those who had either incomplete immunization or had the vaccination three years or more before the actual epidemic. Obligatory vaccination of infants and children from the ages of 6 months up to 12 years and periodic revaccination are of importance in the prevention of diphtheria.

Active Immunization Against Typhoid, Spotted Typhus, Bacillary Dysentery, Tetanus and Influenza. G. M. H. Veeneklaas.—p. 20.

Toxoplasmosis.—Binkhorst reports the probable occurrence of toxoplasmosis in a girl aged 6 years. Many signs characteristic of infantile toxoplasmosis were present, such as psychomotor disturbances, roentgenographically demonstrable intracranial calcifications, microphthalmia and chorioretinitis. The clinical diagnosis was made more probable by the demonstration of toxoplasma-like bodies in the cerebrospinal fluid. This is the first case reported in European literature in which diagnosis was made *intra vitam* and is one of the few nonfatal cases of infantile toxoplasmosis. Moreover, 1 case of hereditary chorioretinitis, 1 case of chorioretinitis in chronic encephalitis and 1 case of encephalitis with chorioretinitis and intracerebral calcifications are described.

Therapeutic Results in Treatment of Urinary Infections in Department for Internal Diseases. L. Loopuyt.—p. 611.
Neurosurgical Treatment of Cerebral Abscess. C. H. Lenshoek.—p. 616.

Chronic Brucellosis.—Gerrits points out that chronic brucellosis closely resembles the onset of pulmonary tuberculosis. He presents histories of 2 patients with recurring hemoptyses. Pulmonary tuberculosis had been suspected, but the condition was diagnosed as chronic brucellosis on the basis of the clinical picture. In the first patient this diagnosis was verified by a positive skin test and in the second by a positive agglutination reaction of 1 : 100 and a positive skin test. The author investigated the possibility of brucellosis in patients in whom tuberculosis had been suspected because of fatigue, night sweats, subfebrile temperature and hemoptysis but in whom tuberculosis could be excluded. In 3 of 66 patients sarcoma, carcinoma and syphilis were detected, but in the others the diagnosis remained obscure. A skin test for brucellosis was positive in 33 of the remaining 63 patients. In some of these patients brucellosis can be diagnosed on the basis of the clinical symptoms. Of 40 patients in whom brucellosis was not suspected, only 3 gave positive skin tests.

Experimental Psychologic Investigations on Astereognosis: Physiology and Pathology of Stereognosis. J. J. G. Prick and P. J. A. Calon.—p. 745.

Pulse and Respiratory Frequency in Malaria.—Van der Kuyp reviews observations on the temperature, pulse rate and respiration of 130 patients with quartan malaria and of patients with tertian or subtertian malaria observed at a hospital in Paramaribo. Pulse and respiration curves showed the quartan, tertian or subtertian type more constantly and more clearly than did the temperature curves. The three curves often supplemented one another in such a way as to make the type of fever clear. The pulse curve sometimes showed the existence of a duplex or triplex quartan infection. During treatment the temperature was the first to become normal. In patients in whom the pulse and respiration did not become normal, a relapse followed. The characteristic course suggests that schizogony on a small scale is responsible for the changes in pulse rate and respiration, because the quantity of liberated toxins is too small to influence the temperature but large enough to influence the pulse and respiratory rate, these being more sensitive to these toxins.

Genesis of Erythroblastosis Fetalis.—Ranström says that since the formulation of the Rh isoimmunization theory of erythroblastosis fetalis, it has usually been referred to as hemolytic disease of the newborn. This theory of Rh isoimmunization raises a number of questions for which there is no satisfactory answer. It remains to be explained (1) why signs of Rh isoimmunization are absent in a number of cases of erythroblastosis, (2) why Rh isoimmunization can be shown to be present without erythroblastosis and (3) why the clinical course of the disease is not satisfactorily explained by the Rh isoimmunization theory. The author regards a placental lesion as an indispensable prerequisite of an isoimmunization and points out that before the Rh theory was advanced a number of observers had noted changes in certain of the endocrine organs. He reports 2 cases which in addition to adrenal hyperplasia and in 1 case of insular hyperplasia in the pancreas showed pituitary changes hitherto not described These pituitary changes consisted of an increase in basophil cells The theory of Rh isoimmunization does not explain the disturbances in the endocrine organs. The author advances the theory that the primary element in the disease is an endocrine dysfunction in the mother, which induces a placental change and changes in the endocrine organs of the fetus (perhaps mainly via its hypophysis), with resulting dysfunctions according to the character of these changes. The data in the literature point to an abnormally high production of estrone or gonadotropic hormone. In some cases, especially in hydrops fetalis, the endocrine disturbances are thought to determine the issue. When the appropriate serologic conditions are present, the placental lesion paves the way for an Rh isoimmunization, which in turn is considered to influence the appearance of icterus gravis and anemia gravis neonatorum. The author outlines an endocrine therapy for erythroblastosis fetalis on the basis of this theory

Acute Benign Mononuclear Meningitis.—Jacobsson reviews observations on 25 cases of acute benign mononuclear meningitis treated at the Gothenburg Children's Hospital since 1922 and presents the case histories for those reported during the past fifteen years. The relations of the disease to poliomyelitis and encephalitis are discussed, it being claimed that no absolutely certain connection between them has heretofore been demonstrated. As a rule the course of the disease is rapid and benign. There is no specific therapy, nor is it necessary.

Gastroduodenal Ulcer in Childhood.—Wamberg reports that a girl aged 9 years had had periodic vomiting for five years and that a girl aged 11 years had had attacks of vomiting for two years as well as periodic, partly tardy pain in the epigastric region and melena twice. Ewald's test meal and x-ray examination revealed a typical duodenal ulcer in both patients. Ulcerations of the stomach and duodenum are most frequently encountered in the first year of life and around puberty. In infancy the ulcers nearly always have appeared in conjunction with infections, intoxications, traumas, circulatory disorders, burns or cachexia. The ulcers occurring in children above 5 years of age in the vast majority of cases are based on gastroduodenitis. The disease may manifest itself by (*a*) a gastroduodenitis syndrome, just as in adults, (*b*) the sudden occurrence of complications (hemorrhage or perforation) and most often by (*c*) vague and atypical symptoms The treatment should be conservative. Gastroduodenal ulcers in childhood presumably occur more frequently than is generally supposed. A more extensive use of x-rays in the examination of children with atypical dyspeptic symptoms would lead to a more frequent recognition of the condition.

Acute Leukemia in Children.—According to Riis, textbooks still describe leukemias as following an acute course, with high fever, hemorrhagic diathesis, necroses in the larynx and oral cavity and having a rapid course. A number of monographs in recent years have shown that this description applies only to the terminal stages of the disease. At the Pediatric Department of the University Hospital of Oslo 24 cases of acute leukemia have been diagnosed between 1937 and 1944. The patients were admitted under various diagnoses such as leukemia, anemia, acute rheumatism, scurvy with anemia, adenitis of the neck, mongolism, bronchopneumonia or disease of the blood. Fatigue, lack of appetite, pallor and fever were the most frequent initial symptoms. Enlargement of cervical lymph nodes and anemia are likewise frequent. In three fourths of the cases the disease began during the first five years of life. The acute leukemia in children as a rule is a myeloblastic leukemia (in at least 21 of 24 cases). In 18 cases sternal puncture was done successfully and revealed up to 99.4 per cent of myeloblasts. The pathologic type of cell was demonstrated in blood-smear preparations of all cases. The number of white cells varied from 1,300 to 185,000.

Schönlein-Henoch's Purpura After Prophylactic Vaccination Against Diphtheria.—Jelke observed a typical case of Schönlein-Henoch's purpura which developed two days after administration of toxoid. In addition to cutaneous hemorrhages there developed edemas of the extremities, articular pains, colic, occult intestinal hemorrhage and hematuria. The cutaneous hemorrhages appeared in successive crops over a period of five months. Patch tests with toxoid were negative, but intracutaneous injection of 0.001 cc. of a toxoid dilution resulted in intestinal hemorrhage, which proved that diphtheria toxoid was the eliciting allergen.

Onset and Prognosis of Nephritis in Children.—Frisk and Klackenberg thought that follow-up examinations a sufficient number of years after the onset of nephritis would throw light on the prognosis. Their studies were made on 239 patients, of whom 96 per cent were still alive from ten to twenty years after the first hospital treatment. In addition to the ordinary tests, quantitative sediment counts by Addis's method were made. Ninety per cent of the patients with acute nephritis, most of whom had had a hemorrhagic onset, had recovered. Slightly more than 5 per cent had permanent renal damage, and somewhat less than 5 per cent were borderline cases, where further investigation would have been necessary for definite classification. An unnoticed insidious onset was combined with bad prognosis. This form of the disease, termed primary chronic, led to death within five years. This type of onset is not common, accounting for only 11 cases. The secondary chronic, on the other hand, influenced the general state of health surprisingly little over a long period. Acute convulsive uremia and the extent of the initial albumin did not influence the prognosis, nor did tonsillectomy.

Significance of Positive Takata Reaction.—Fløystrup reports that the Takata reaction was positive in 100 of 5,825 serums. In 83 cases injury of the liver parenchyma was established, hepatitis in 71, cirrhosis of the liver in 8. In 7 of the remaining 17 cases there was congestion of the liver. Of the 35 cases with maximal precipitation 29 were due to chronic hepatitis and 3 to cirrhosis of the liver. Although many serums must have come from patients with cholelithiasis, no positive reactions were recorded in these.

Takata Reaction in Extrahepatic Disorders.—Lange says that of 123 cases with positive Takata reactions about three fifths appeared in extrahepatic disorders, especially in chronic, nonspecific pulmonary diseases. A positive Takata reaction in pulmonary disorders is an unfavorable prognostic sign.

Book Notices

Biochemistry of Cancer. By Jesse P. Greenstein, Head Biochemist, Chairman, Section on Biochemistry, National Cancer Institute, National Institute of Health, United States Public Health Service, Bethesda, Maryland. Cloth. Price, $7.80. Pp. 389, with 39 illustrations. Academic Press, Inc., 125 E. 23d St., New York 10, 1947.

This book, which comprises in good part the extensive investigations of the author and others at the National Cancer Institute, discusses biochemical studies in the field of cancer research which have yielded results of interest and significance. As stated by the author in the preface, a desire to show the reader the tremendous gaps that exist in our knowledge and to illustrate the possibilities of reciprocal enrichment in the fields of normal and abnormal cell physiology are brought home.

The material is presented in four general categories, on general phenomena and taxonomy of cancer, the induction of tumors including extrinsic and intrinsic factors, attempts at control of tumor induction and growth by nutritional, endocrinologic and chemotherapeutic means, and the properties of tumors, which is divided into a long chapter on the chemistry of tumors and another on the chemistry of the tumor bearing host.

The second chapter, on the general phenomena and taxonomy of cancer, deals briefly with some characteristics of tumors and their transmissibility, and on the development and use of inbred strains of mice for experimental cancer research. The discovery of the carcinogenic polycyclic hydrocarbons and their many synthesized derivatives is discussed in relation to their comparative carcinogenic action in different sites of the body of many strains of mice, in chapter 3. Also the interesting problem of their metabolism is discussed and the dosage of and response to them in various organs of mice of inbred strains under many experimental conditions is given. A brief summary of the large amount of information on the azo dyes and their derivatives which are widely used as carcinogenic agents is well summarized.

The role of intrinsic factors, or those possessing a biogenic origin, which deal largely with the influence of sex hormones on the development of cancer of the sex and accessory sex organs, is delineated in chapter 4. Also the effect of intrinsic influences on the development of lymphoid tumors and their effect on liver and kidney arginase is given. The chapter is completed with a summary of the role of milk factor in mammary carcinogenesis in mice and of the well known viral origin of fowls and of the Shope rabbit papilloma. The nutritional, endocrinologic and chemotherapeutic approaches for their effects on tumor induction and on tumor growth are concisely and well summarized in the next three sections.

Especially interesting to biochemists engaged in cancer research or enzymology, and probably the most important chapter in the book, is the one on the chemistry of tumors, a large portion of the investigations being those of the author. From a comparison of many enzymes studied in different normal tissues and their corresponding neoplastic growths, especially liver and hepatoma, the general conclusions—that tumors have qualitatively the same enzymes as normal tissues, that tumors tend to resemble one another chemically more than they do normal tissues, that a normal tissue in becoming cancerous may lose some of its specific functions altogether or contain them to a less degree than normal, and that tumors tend to converge to a common type of tissue—are of great value in a clarification of the conception of carcinogenesis.

The final chapter is on the effects produced in an animal as a consequence of the presence of a tumor; to those not aware of this phase of cancer research the results will be most enlightening. The effect of various tumors transplanted under the skin on lowering the hepatic and renal catalase, d-amino acid oxidase and arginase is quite dramatic. The possibility of using these changes or, better yet, of searching for possible subtle blood changes caused by transplanted and induced tumors for diagnostic purposes will be of obvious importance to all.

The size and format of the book are convenient and it appears to be relatively free of errors. It will serve as an excellent reference work for the student interested in cancer research, though in some phases it is not complete.

Concise Chemical and Technical Dictionary. Edited by H. Bennett, Technical Director, Glyco Products Co., Inc. Cloth. Price, $10. Pp. 1,055. Chemical Publishing Co., Inc., 26 Court St., Brooklyn 2, N. Y., 1947.

This type of book, if properly presented, is a useful addition to medical libraries. The student, teacher and physician today need information on a variety of chemical and technical subjects that have come about because of modern research. As soon as new ideas and substances are found to have practical value in medicine, the medical profession is introduced to new terms. The best sources of information frequently are not available and, if they are, contain detailed information that is not generally needed for the practitioner unless he has a special interest in the subject. The research worker, however, must refer to original publications. To meet such a need dictionaries can serve a useful purpose. However, they must be reasonably complete, accurate and informative to be useful for those interested in medicine. Bennett's Concise Chemical and Technical Dictionary cannot be regarded as satisfactory for this purpose, although it may have limited usefulness for those who want only casual information. Critics will not be satisfied with some of the definitions; the scope is not adequate and in a number of instances there is an unnecessary and perhaps confusing repetition; cross references are not always complete; there are various abbreviations that are not, so far as chemists are concerned, in common use, for example M. A. R., I. R., I. V. and I. W. It is disconcerting to look for a definition of bougie and be referred to "pencil" and not able to find a definition for pencil. It is rather irritating to find valuable space taken by definitions for words such as "tweed," which can hardly be classed as a word normally found in a chemical and technical dictionary unless the volume is of considerable size. Such a book as this could be much more useful if it were more complete and contained information that would reveal to the reader whether the name is protected or a common or generic name, what firm holds the name, more information on cosmetics, and whether the book is limited to the class of readers for which it is written; it is difficult to write a chemical and technical dictionary "for both professionals and laymen." About 50,000 definitions are claimed to be included in the volume, but they do not as stated "cover every field of scientific and technical development" except in a broad way. Pharmacists, physicians and those interested in cosmetics would like to see a better definition, for example, for night cream than "greasy type of cosmetic cream" and for penicillin "antibiotic substance found in the filtrate of a broth culture of Penicillium notatum." There might also be consistency in describing the uses of a compound; they could either be omitted or made more complete; for example, barbital is "used in medicine," while barbital soluble is "used as sedative, hypnotic." The author is to be commended for his attempt to undertake such a project; a book of this type is always needed. Unfortunately, however, as far as the medical profession is concerned, the results of the author's efforts cannot be as highly commended.

Pre-Frontal Leucotomy in 1,000 Cases. Great Britain, Board of Control (England and Wales). Paper. Price, 6d. Pp. 31. British Information Services, 30 Rockefeller Plaza, New York 20; His Majesty's Stationery Office, York House, Kingsway, London, W. C. 2, 1947.

Prefrontal leukotómy has been adopted on a fairly large scale in England as a method of treatment for mental disorders that have proved refractory to other methods. This is a report by the Board of Control covering results in 1,000 cases from forty-three different hospitals. Thirty-five per cent of the patients have been discharged, and 32 per cent are improved though still remaining in the hospital. The operative mortality is 3 per cent, mostly due to hemorrhage. Only 1 per cent of the patients are considered worse as the result of operation. These figures, gratifying as they are, hardly tell the whole story in terms of relief from intolerable preoccupations and misery on the part of the patients and of reduction in dangerous and disturbed behavior on the part of hospital inmates. Only the most difficult patients have been subjected to leukotomy.

In the small monograph the figures are broken down as regards age, sex, diagnosis, duration and so on. Results are better in older patients with shorter duration and in the affective group rather than the schizophrenic. Leukotomy (lobotomy in this country) is particularly effective in relieving mental tension and depression, while hallucinations and delusions react less favorably. Relapses are of moderate frequency; epileptic fits and other complications are not very uncommon aftermaths; 242 patients are listed as "citizens" able to earn a living or keep house. While some brilliant results are reported in patients that have been institutionalized for a number of years, the striking feature of the report is the large number of successful results in those operated on within two years of the onset of the disease. Taking only the early cases, 50 per cent of the schizophrenic and 65 per cent of the manic-depressive group are discharged recovered if operated on within two years. The percentages fall to 10 or 15 in those operated on five years or more after onset. Even so, the improvement in hospital adjustment in these chronic cases runs around 40 per cent. "Remarkable improvement in behavior follows in a large percentage of cases who have had severe symptoms with poor prognosis and have failed to respond to other methods of treatment. Many are discharged from the hospital and others, while unfit to leave, become much more placid and easier to nurse. The question of whether or not these results are achieved at the cost of the loss of some finer mental qualities is not yet answered and further study is needed on this most important point."

This study, documented by several tables, answers many of the questions that are being asked concerning the surgical treatment of mental disorders. Other questions are propounded, but in view of the difficulties presented in gathering the material they can probably be answered better by individual investigators who follow their cases for long periods.

Chemotherapy Yesterday, To-Day, and To-Morrow. By Sir Alexander Fleming, M.B., F.R.C.S., F.R.C.P., Professor of Bacteriology, University of London, St. Mary's Hospital, London, W. 2. The Linacre Lecture Delivered at Cambridge on May 6, 1946. Paper. Price, 50 cents; 2s. Pp. 39, with 7 illustrations. Macmillan Co., 60 Fifth Ave., New York 11; Cambridge University Press, Bentley House, 200 Euston Rd., London, N. W. 1, 1946.

This is the Linacre Lecture of 1946 delivered at Cambridge University by the discoverer of penicillin. In discussing chemotherapy of the past, Fleming alludes to the observations of Pasteur, Lister, Ehrlich and himself. Fleming considers as his most important investigation work carried out in 1924 relating to the destructive action of antiseptics on the blood leukocytes. Leukocytes are essential for the phagocytosis and destruction of bacteria. Unfortunately, chemicals then available were not specific for bacteria alone but also destroyed the leukocytes. This work clearly defined the attributes of the ideal chemotherapeutic agent, one that would have a specific action against bacteria without altering the function of the host's tissue and blood cells. The sulfonamides constituted a definite step forward in pursuit of the ideal agent, but penicillin represents a highly potent antibacterial agent having surprisingly few toxic effects. Without any doubt, the earlier studies of Fleming alerted him for the potentialities of a fungus which appeared to destroy staphylococci on an agar plate. He concludes his lecture by appealing for the establishment in England of an institute of general microbiology in which the various disciplines of biology would be represented. This brief summary of chemotherapy should appeal to any one interested in the field.

The Nervous Child. By Hector Charles Cameron, M.A., M.D., F.R.C.P., Consulting Physician to The Children's Department, Guy's Hospital, London. Oxford Medical Publications. Fifth edition. Cloth. Price, $3. Pp. 252, with illustrations. Oxford University Press, 114 Fifth Ave., New York 11; Amen House, Warwick Sq., London, E. C. 4, 1946.

Since the first edition in 1919, many advances have been made in diagnosis and management of the so-called nervous child. The early chapters, on doctors, mothers and children, observations in the nursery, management and conduct, want of appetite, indigestion and want of sleep, are still as acceptable today as formerly, but there are several later chapters which are quite unscientific, outdated and in need of thorough revision. Formerly there were few good books in this field. There are now many which are more complete and are able to replace the old textbooks.

Essentials of Physiological Chemistry. By Arthur K. Anderson, Professor of Physiological Chemistry, The Pennsylvania State College, State College, Pennsylvania. Third edition. Cloth. Price, $3.50. Pp. 395, with 38 illustrations. John Wiley & Sons, Inc., 440 Fourth Ave., New York 16; Chapman & Hall, Ltd., 37-39 Essex St., Strand, London, W. C. 2, 1947.

This volume has been revised, and certain sections have been rewritten. The text contains materials essential to students for a short course in chemistry entering medicine, bacteriology, nutrition and allied sciences. A discussion of optical isomerism has been brought up to date, glyceric aldehyde rather than lactic acid being used as an example, carbohydrate metabolism has been further developed and the section on chemotherapy, which contains newer drugs and antibodies, has been expanded. The vitamins have been brought up to date, and a chapter on blood has been added. The volume will be a good addition to a collection of books on physiologic chemistry.

Obstetricia de urgencia: Sindromes hemorragicos. Por los doctores Diego Taylor Gorostiaga, profesor suplente de clínica obstétrica normal y patológica de la Facultad de ciencias médicas de la Universidad nacional de La Plata, y Roberto Enrique Lede, jefe del servicio de obstetricia y ginecología del Hospital Petrona Villegas de Cordero. Prologo del Prof. Dr. Victorio Monteverde, profesor titular de clínica obstétrica normal y patológica de la Facultad de ciencias médicas de la Universidad nacional de La Plata. Paper. Pp. 419, with 103 illustrations. López & Etchegoyen S. R. L., Junín 863, Buenos Aires, 1946.

This book deals with obstetric emergencies. In the sixteen chapters the authors describe, illustrate and discuss the etiology, diagnosis and treatment of abortion, hydatid mole, ectopic pregnancy, placenta previa, abruptio placentae, acute torsion of the gravid uterus, rupture of the uterus, postpartum hemorrhage, bleeding elsewhere than from the uterus, inversion of the uterus and shock. An entire chapter consisting of fifty-five pages and twenty-seven illustrations is devoted to blood transfusion and the use of plasma. The text is written with simplicity, and the illustrations are numerous, clear, instructive and presented in an interesting fashion. The advice given by the authors is practical and apparently is based on an extensive experience. However, the Braxton Hicks version should be given up for the treatment of placenta previa because it is dangerous and intrauterine douches should have no place in the treatment of profuse uterine bleeding because, while the douche is being prepared and given, valuable blood is being lost. There are much quicker and more certain means of controlling uterine hemorrhage than intrauterine douches. The contents of this book may be found in all the standard textbooks of obstetrics, but it does bring together most of the emergency conditions that occur during pregnancy. For this reason it serves a useful purpose and is worthy of possession and study.

The 1946 Year Book of General Therapeutics, November, 1945-August, 1946. Edited by Oscar W. Bethea, Ph.M., M.D., F.A.C.P. Fabrikoid. Price, $3.75. Pp. 443, with 20 illustrations. Year Book Publishers, Inc., 304 S. Dearborn St., Chicago 4, 1946.

Those who are familiar with the Year Book of General Therapeutics will find in the 1946 volume essentially the usual approach for this series to therapeutic highlights for the year, in this case extending from November 1945 to August 1946. For others who have yet to make an acquaintance with the book, it may be pointed out that it consists essentially of an abstracting of current medical literature published during the year. Included are discussions of sulfonamides, sulfones, penicillin, streptomycin, amebicides, burns, antimalarials, antisyphilitics, antirheumatics, gout, serums and plasma, vaccines and other drugs such as folic acid, amino acids, hormones, vitamins, thiouracil, sedatives and those acting especially on the heart and blood vessels. If a reader wishes to have available a ready source of fairly comprehensive abstracts the Year Book will provide much help. If a reader wishes to be guided in his choice of therapy he may have to go elsewhere, as abstracts of various papers sometimes present conflicting views and, of course, occasionally present views not yet generally adopted or later disproved. There are many, however, who come to regard the Year Book series as useful additions to their libraries, and these persons will not be disappointed in the 1946 Year Book of General Therapeutics; it again provides what has come to be expected.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST

AIR TRAVEL AND HYPERTENSION

To the Editor—A woman aged 65 wishes to fly from Boston to California She has arthritis, with a blood pressure of 238/120 Could or would such a thing as hitting an air pocket cause untoward effects and possible cerebral vascular episode? Disregarding the arthritis, would her blood pressure or hypertension rule out air transportation?

David Glunts, M D , Roxbury, Mass

ANSWER—Transcontinental flying, which involves ascent to considerable altitude in crossing the Rocky Mountains, is inadvisable for a patient of 65 with hypertension of the degree mentioned in the query While it is quite possible that the trip could be made without lasting injury, the probability of intracranial or cardiac difficulties is sufficient to advise against the undertaking Histanoxia of tissues distal to the constricted arterioles is the chief source of injury to parenchymal tissues in hypertensive disease, the lowered oxygen tension of fairly high altitude flying may well be just enough to lower the oxygen supply to the brain or myocardium below critical levels This hazard is intensified if the patient is also anemic or if her hypertensive disease has progressed to arteriosclerosis Furthermore, the anxiety and excitement of such a trip can well lead to a transient but dangerous exacerbation of the hypertension Travel in a railroad compartment is the safer method for this patient

DIPHTHERIA TOXOID

To the Editor—In the care of men and women of college age, how soon after initial immunization for diphtheria with alum precipitated diphtheria toxoid should a booster dose be given, continued at what intervals and what dose used?

F F Ebersole, M D , Mount Vernon, Iowa

ANSWER—If negative Schick reactions have been obtained following immunization with alum precipitated toxoid, a booster dose would not ordinarily be given to men and women of college age However, if diphtheria was prevalent in the community it would be well to perform Schick tests annually, and then a booster dose of alum precipitated diphtheria toxoid might be given to those who had positive Schick reactions Under such circumstances, 1 cc of alum precipitated toxoid may be injected subcutaneously Nevertheless, it has been found that as little as 0 1 cc of plain diphtheria toxoid intracutaneously is sometimes sufficient to bring about a change from a positive to a negative Schick reaction

The duration for diphtheria immunity is greatly influenced by the number of injections of toxoid When three doses are administered at four week intervals, immunity persists in more than 90 per cent of the cases for a period in excess of four years

TIDAL WATER AND POLIOMYELITIS VIRUS

To the Editor—I should be grateful for information as to any recent publication concerning water-borne diseases What I have in mind is the relationship of various infections to polluted public waters, such as our Narragansett Bay, parts of which have recently been closed to shellfishing, bathing and other uses because of increasing contamination from untreated and imperfectly treated sewage Contamination of the water supply for domestic use is not under consideration Has any work been done that would indicate that salt or tidal water can spread the virus of poliomyelitis?

Paul C Cook, M D , Providence, R I

ANSWER—The broad question of water contamination is amply covered in most textbooks on hygiene or water purification

The second more specific question is "Can salt or tidal water spread the virus of poliomyelitis?" There has been much effort made to implicate water as a factor in the spread of this disease Kling in Sweden claims to have recovered the virus from water These claims have not been substantiated Water obtained in streams or bays into which raw sewage is emptied has been found to be contaminated (Detroit and Charleston) but not for long, and the virus is soon diluted to a point where it must be of little epidemiologic importance Swimming pools and drinking water have been investigated many times with fruitless results

It has not been proved that water carries virus, and even though water did carry virus it would be of little epidemiologic importance

DERMATOLOGY AS A SPECIALTY—FIRST DERMATOLOGIC AUTHORITY

To the Editor—Will you kindly inform me as to when dermatology first became recognized as a separate specialty and name the first man who became a recognized authority on dermatology?

Wallace E Hopkins, M D , Dallastown, Pa

ANSWER—The first question as to when dermatology first became recognized as a separate specialty cannot be answered in one or two words The recognition of the specialty was a gradual process lasting years and varied in different countries For instance, the founder of French dermatology, as stated in Pusey's "History of Dermatology," was Antoine C Lorry (1726-1783) It is generally accepted that the founder of British dermatology was Robert Willan (1757-1812) Dermatology was certainly recognized as a specialty in the United States in 1876, when the American Dermatological Association was founded However, the first group of dermatologists to organize was the New York Dermatological Society in 1869, largely by men who had had their special training abroad

To name the first man who became a recognized authority on dermatology is even more difficult The honor should probably go to Jean Astruc (1684-1766), who was a brilliant man, a physician to the king in Paris, and a teacher of Lorry

ANTHRAX IN ELEPHANTS

To the Editor—Because of a fatal case of anthrax that has come to my attention may I ask whether there have been any human cases of anthrax traced to infection in elephants? Specifically, have human cases of anthrax been traced to work (such as cutting or carving) with elephant tusks imported from Africa?

Roy M Seideman, M D , West Hartford, Conn

ANSWER—Reference to human cases of anthrax traced to elephants cannot be found No cases of human anthrax are known to have occurred in Africa as a result of working with elephants or from handling elephant tusks

G H Evans reports anthrax as relatively common in elephants in India

African elephants in the Belgian Congo are considered little subject to Bacillus anthracis infection "Symptomatic anthrax" caused by Clostridium chauvoei does occur in hippopotamuses in the Belgian Congo Considering the wide range of animals susceptible to anthrax, its prevalence in certain areas and the ability of anthrax spores to remain infective for long periods of time, it is not beyond the realm of possibility for anthrax to result from handling elephant tusks Tusks are invariably grooved, pitted and cracked and could conceivably harbor anthrax spores

SPASM OF ACCOMMODATION

To the Editor—What should be done for patients with *spasm of accommodation*? In a woman retinoscopy reveals plus 150 sphere each eye with working distance deducted All that she will accept is a plus 50 sphere right eye and plus 25 sphere left eye She already has been fitted with six pairs of glasses by six different doctors These lenses range from plus 2 spheres down to plus 25 sphere each eye

Donald Brink, M D , Hutchinson, Minn

ANSWER—On the basis of the information given in the query, it is not possible to establish a diagnosis of spasm of accommodation, which is an exceedingly uncommon condition A certain degree of sustained accommodation is frequently seen in young hypermetropic persons and may be considered a physiologic adaptation in the interests of clear vision

Excessive contraction of the ciliary muscle causes a relative myopia, increased actual myopia or increased latent hyperopia It may be caused by miotics, drugs such as arsenic and the sulfonamides, ocular injuries and conditions causing irritation of the ciliary body Most authorities indict excessive near work, defective illumination, uncorrected refractive errors, general debility and unstable disposition Diagnosis is based on the observations of loss of accommodative amplitude, nearing of the far point and disappearance of the refractive abnormality with cycloplegia

Treatment should be directed toward determination of the refractive error with full cycloplegia using atropine if necessary, and the prescription of the full correction as found with the ciliary muscle paralyzed In hypermetropic patients about 1 diopter is deducted to allow for the normal physiologic tone of the ciliary muscle Many patients will require instillation of homatropine solution for a week or two after glasses are prescribed to allow recovery of the ciliary muscle from its condition of irritability Near work should be forbidden for a time, its amount should be curtailed thereafter, and the general health should receive attention

TREATMENT OF CONCURRENT CARDIOVASCULAR AND NEUROSYPHILIS

To the Editor:—A man aged 51 was referred to a neuropsychiatric clinic because of convulsions and transient episodes of confusion. A diagnosis of dementia paralytica was established on the basis of typical spinal fluid findings. In addition, the patient had cardiovascular findings strongly suggestive of aortic insufficiency and syphilitic aortitis. There was no evidence of decompensation. The blood pressure was 142/20 in the left arm (in the sitting position) and 124/26 in the right arm. What treatment is indicated? Is penicillin contraindicated because of the cardiovascular involvement? Is the use of the hypertherm or of malaria contraindicated?
Fred P. Pokrass, M.D., Norristown, Pa.

ANSWER.—Treatment of active cardiovascular syphilis with a rapidly spirillicidal drug such as penicillin or neoarsphenamine or a phenarsine derivative will frequently cause sufficient cardiac damage from therapeutic shock or paradox to result in cardiac decompensation or even, though less frequently, in sudden death. The danger of using penicillin in the presence of active cardiovascular syphilis was reported by Dolkart and Schwemlein in THE JOURNAL, October 13, 1945.

Although reports of this sort are not as yet frequent in the literature, probably because of the recent introduction of penicillin in the treatment of syphilis, similar cases, reports of which have not been published, have occurred.

When confronted with concurrent cardiovascular syphilis and neurosyphilis, one should make a careful appraisal of the relative seriousness of the two complications in the individual case, together with a study of previous therapy for syphilis if any. If there has been several months of antisyphilitic therapy recently, or if there is reason to think that the cardiovascular involvement is at present inactive, there would be less danger from the use of a trivalent arsenical or from penicillin. If there has been no preparatory treatment, the risk from the immediate introduction of these drugs would be great.

In general, life expectancy from severe cardiovascular syphilis with aortic regurgitation is less than from central nervous system involvement. An effort must be made, therefore, to find a treatment for the nervous system which will not injure the heart and great vessels but will rather assist in its arrest. Tryparsamide in dosage of 2 to 3 Gm. once a week intravenously will answer the purpose of treating the central nervous system without injuring the heart. A pentavalent arsenical such as tryparsamide has little effect on the cardiovascular system. Its use could be accomplished with courses of bismuth subsalicylate intramuscularly for the cardiac involvement given once a week for eight to ten weeks with a rest period of six to eight weeks between courses. It would be best to start with subtherapeutic doses of the bismuth preparation, perhaps 0.5 to 1 cc. (30 to 60 mg. of bismuth metal) once a week for the first six to eight weeks before increasing to a full weekly dose of 2 cc. (120 to 130 mg. of bismuth metal) After four to six months of such treatment, if it is well tolerated, the cardiovascular process should be rendered less active and it might be possible, after consultation, to consider the cautious use of penicillin at that time for the central nervous system involvement if the progress with tryparsamide has not been satisfactory. Involvement of the optic nerve is, of course, a contraindication to the use of tryparsamide, but the risk here also would have to be weighed in the light of the other activity described.

There is no absolute contraindication to the use of fever therapy in a case such as the one described in the query. In fact, patients with minor degrees of cardiovascular involvement and even with aneurysm tolerate fever therapy well if they are not decompensated. Such a decision depends on individual appraisal of the patient, however, and in general it would be safer to employ tryparsamide rather than malaria or hyperthermy in treating a patient with severe aortic regurgitation.

FLEXIBLE KONE DIAPHRAGM

To the Editor:—What is the general opinion among competent gynecologists as to the use of rubber cervical diaphragms which are known as "flexible kone diaphragm."
R. P. Fruehauf, M.D., Superior, Wis.

ANSWER.—As far as is known, no competent gynecologist or any other physician has published a paper on the use of the "flexible kone diaphragm." No physician's name is mentioned in the advertising circulars concerning the diaphragms, so most likely there have not been any scientific publications about this instrument. The points of merit claimed by the manufacturers for the flexible kone diaphragm are that (1) it is easy to apply, (2) it is easy to remove, (3) it is scientifically correct, (4) it is nonirritating, (5) it is comfortable while in use, (6) it is noninjurious, (7 there are no troublesome after-effects and (8) it may be kept in stock for three years without loss of resiliency. The stem of the flexible kone diaphragm consists of a flexible chromium wire coil spring covered with soft para rubber. A soft pliable rubber cap is attached at the lower end of the stem and soft rubber oval cones are fastened to the stem.

The manufacturers of the flexible kone diaphragm also make and sell the flexible kone pessary, which "consists of a framework of especially made pliable, rustless chromium wire of small diameter covered with a coating of pure soft rubber, approximately 1⁄32 of an inch thick. At one end of the pessary are two prongs and at the other end is a soft rubber button about the size of a nickel. On the stem (1¼ inches in length) are three soft rubber cones so placed as to fit the fusiform canal of the cervix. . . ."

Reports in the literature have pointed out the dangers attending the use of intrauterine wishbone pessaries. These are foreign bodies which often lead to infection of the uterine cavity, tubes and peritoneum. There is also risk of perforation of the uterus. In some cases the prongs become embedded in the uterine wall. Extrauterine pregnancy as well as intrauterine gestation has occurred in the presence of a stem pessary.

While the 1⁄32 inch rubber covering of the chromium wire may add some protection, the insertion of the instrument within the cervix or in the cervical canal and uterine cavity places it in the category of objectionable foreign bodies capable of doing harm.

J. P. Greenhill (1939 Year Book of Obstetrics and Gynecology, p. 411) says that "all gynecologists are agreed on the harmfulness of paraphernalia which is placed in the cervical canal or uterine cavity for purposes of preventing conception. Not only may these devices be harmful and occasionally fatal but they are by no means certain in preventing conception. Therefore, because of their ineffectiveness and their great danger and because there are many far simpler and safer procedures, mechanical devices should never be inserted into the cervical canal or the uterine cavity for the purpose of preventing conception."

CHOICE OF ESTROGENIC COMPOUND FOR MANAGEMENT OF MENOPAUSE

To the Editor:—A woman aged 53, fout years past the menopause, is able to control hot flashes and palpitations by diethylstilbestrol 0.5 mg. every other night. In two weeks' time, however, "spotting" begins and lasts until the diethylstilbestrol is discontinued. Increased dose results in increased flow. Physical and gynecologic examination is otherwise negative. Is there any other estrogen, preferably oral, that does not have this effect? Is it advisable to do a diagnostic curettage in this case? If so, how soon after discontinuing diethylstilbestrol should this be done? Is it safe to continue this medication despite bleeding?
M.D., California.

ANSWER.—There is a rather large number of compounds which possess estrogenic effect and may give relief to women who are suffering from the menopausal syndrome. These compounds are not necessarily related chemically but they still have this therapeutic effect in common. Nevertheless there are minor qualitative variations in their physiologic effects on tissues. For example, estradiol will enhance the effect of progesterone on the endometrium under certain conditions, while diethylstilbestrol may actually inhibit the action of progesterone. There seems to be a definitely higher incidence of estrogenic bleeding in the menopausal patient on diethylstilbestrol than with most other estrogens. The production of hyperplasia of the endometrium seems also to be more easily accomplished with diethylstilbestrol than with some of the other compounds. The exact reasons for this are not well known, but it is acknowledged that diethylstilbestrol has a somewhat different metabolic fate than the natural estrogens such as estrone and estradiol. It is therefore suggested that to avoid uterine bleeding other oral estrogens be used such as estrone sulfate, benzestrol or ethinyl estradiol. It is also suggested that some of the injectable diethylstilbestrol compounds such as the propionate or the palmitate may be found effective in controlling the patient's symptoms and still not produce the unwanted uterine bleeding. This may appear confusing, but it should be remembered that these compounds are absorbed slowly from the site of injection and the effective amount in the blood stream at any one time is probably small and will not produce bleeding because this phenomenon seems related to the rapid absorption of estrogens, with the development of sharp peaks in estrogen blood levels.

It is not wise to continue diethylstilbestrol by mouth while the patient is bleeding from the uterus, since hemorrhages may actually occur under these conditions. Four to five weeks after discontinuing diethylstilbestrol should be sufficient time before the new oral estrogens are attempted or the injectable estrogens administered. There appears to be little need of a curettage if the physician is convinced that the cause of the bleeding is due to estrogen therapy.

TURPENTINE FUMES AND REACTIVATION OF TUBERCULOSIS OF KIDNEY

To the Editor.—A man aged 45, a painter in previous good health, while working in a closed room using oil and turpentine paints became violently ill from the fumes, resulting in severe renal irritation, including classic symptoms of nephritis and cystitis. He never recovered his health and subsequently, within a period of weeks, was found to have a flare up of an old healed renal tuberculosis. Roentgenograms of the lungs did not reveal any pulmonary tuberculosis. He underwent a nephrectomy, and subsequent repeated cultures of the urine did not show further tuberculosis either of the bladder or of the surviving kidney. He still has frequency of urination and some suprapubic discomfort, but cystoscopy does not show gross pathologic changes. His claim for compensation was turned down and he is now appealing the case. Granted that tuberculosis is caused by the Mycobacterium of tuberculosis, would acute turpentine (and other paint solvents) nephritis cause the exacerbation of the latent renal tuberculosis? Would cystitis caused by turpentine explain the continued bladder symptoms, since further genitourinary tuberculosis has been ruled out?

M. D., Arizona.

Answer.—There is no doubt that turpentine absorbed in sufficient amounts can cause severe acute renal damage with parenchymal necrosis and hemorrhage. Irritation of the lower urinary tract, including the bladder, is also an accepted fact. The question of the relation between the acute injury of the kidney by turpentine and the flare-up of an old healed renal tuberculosis cannot be answered without more detailed knowledge of the type of renal tuberculosis, of the evidence for its healed state and of the appearance of the gross and microscopic changes in the removed kidney. As in the case of the relation of trauma to tuberculosis, two mechanisms for reactivation of the infection are possible: (1) the local extension of tuberculosis from a latent focus due to direct injury of surrounding tissues and the opening up of pathways for the spread of tubercle bacilli, (2) the flare-up of local infection due to lowering of the patient's general resistance.

It is therefore debatable whether severe turpentine injury of the kidney might have damaged the region surrounding the old tuberculous focus enough to initiate a rapid local spread, or whether the deleterious general effects of turpentine poisoning lowered the patient's resistance and thereby led to the reactivation of the renal tuberculosis. The time interval between the onset of symptoms due to turpentine and the flare-up of the renal tuberculosis would seem to be appropriate for a causal connection between them, assuming that the patient was really free from symptoms of active renal tuberculosis previously.

The continuing bladder symptoms could scarcely be attributed to the original irritation by turpentine in view of the absence of objective findings and the lapse of time. Some other cause, including the possibility of a functional basis, should be considered.

The possibility that other paint solvents were responsible for the renal irritation is rather remote. At any rate, turpentine by itself could easily account for the symptoms.

SEMINAL FLUID EXAMINATION, EFFECT OF ABSENT TESTIS OR VARICOCELE

To the Editor.—What is the accepted "rough" method of making a sperm count which can be used in office practice? What are the limits of normal and the accepted criteria for determining whether a male is fertile? Does loss of one testis lower the sperm count? Would a symptomatic varicocele lower the sperm count? M. D., Pennsylvania.

Answer.—There is no "rough" method of making an examination of the seminal fluid to determine whether or not a man is fertile. The accepted procedure for seminal fluid analysis is as follows: After the man has abstained from sexual intercourse for five to six days, the seminal fluid is collected in a small beaker by having the patient ejaculate the semen directly into the container by artificial means. Condom specimens are not accurate. After liquefaction of the seminal fluid has occurred, which in normal specimens is from ten to fifteen minutes, the amount of semen is accurately measured in cubic centimeters. A small drop is then placed on a glass slide and sealed with a cover slide. The motility and percentage of active spermatozoa are estimated by using the high dry objective. Pus cells and bacteria are searched for. In normal specimens about 80 to 90 per cent of the spermatozoa show active motility. The longevity of the spermatozoa can be determined by drawing a small amount into a fine glass tube, sealing both ends, placing it in a refrigerator and making routine observations. Under ordinary ice box temperature, spermatozoa will be active after twenty-four to forty-eight hours.

To count the spermatozoa a sample is drawn up to the 0.5 mark in the white cell counting pipet while it is held nearly horizontal. A solution containing 1 per cent solution of formaldehyde and 5 per cent sodium carbonate in water is then drawn up to the 11 mark. The dilution is 1:20. A drop of the diluted seminal fluid is allowed to flow under the cover glass of the counting chamber. After allowing about five minutes for settling, one counts all the spermatozoa in the four large squares (each one 1 mm. square and 1 mm. deep), using the high dry objective. The total number of spermatozoa counted is then multiplied by 20 (for dilution) divided by 4 (number of cells counted) multiplied by 10 (for cubic millimeters, since the depth of the counting chamber is 0.1 mm.) and by 1,000 for cubic centimeters. The result obtained is the number of spermatozoa in 1 cubic centimeter. To obtain the total number of spermatozoa ejaculated, the number in 1 cc. of seminal fluid is multiplied by the volume of seminal fluid. Normal specimens contain around 100,000,000 spermatozoa per cubic centimeter, or a total number of 250,000,000. A fertile man should have at least a total of 100,000,000 spermatozoa. However, there are many other factors besides the number of spermatozoa that enter into a normal seminal fluid. The morphology of the spermatozoa should be studied, for this there are many different staining methods which can be obtained in any of the standard textbooks on fertility.

The absence of one testis, if the other one is normal, will not appreciably influence the total number of spermatozoa. Varicocele would lower the spermatozoa count if the testis on the side of the varicocele is not normal and the other testis is abnormal. However, if the other testis is normal and the seminal fluid analysis is within normal limits, the patient is potentially fertile.

MAGNESIUM SULFATE FOR VERTIGO AND MENIÈRE'S DISEASE

To the Editor.—A patient with severe vertigo has been treated and reports cure from the intravenous injection of 50 per cent solution magnesium sulfate 2 cc. three times weekly and ammonium chloride by mouth. She stated that during injection she felt as if she was burning up, but this passed off in a few minutes and she felt perfectly well, having no more dizziness for some months. Is the intravenous injection of magnesium sulfate in this manner beneficial and safe?

M. D., Indiana.

Answer.—Magnesium sulfate has not been used extensively in the treatment of vertigo. Its dominant action physiologically consists of depression and inhibition. Given parenterally it has a diuretic effect. The magnesium ion is toxic when high concentrations accumulate in the extracellular fluid. If the kidneys are functioning in a normal manner magnesium is so rapidly excreted that change in blood level of the ion cannot be detected. The drug should not be employed in subjects who have renal insufficiency.

Schick reports its use in the treatment of 18 subjects with Meniere's syndrome who apparently had been refractory to other forms of treatment. The treatment consisted in intravenous injections of 5 cc. of 50 per cent magnesium sulfate solution administered two or three times weekly. The number of injections ranged from ten to twenty, depending on the response and the severity of the symptom complex in each individual. Each injection was administered at an extremely slow rate with the patient in the recumbent position. By carefully observing these precautions the patients did not observe any ill effects from the drug.

Of the 18 patients treated, 7 did not experience attacks during a control period of fourteen months, 7 noted definite improvement and 4 noted no change.

AMPHETAMINE COMPOUND AND WEIGHT REDUCTION

To the Editor.—What is the value of dexedrine sulfate, recommended to curb the appetite in cases of obesity? Is it safe? I realize that dietary restriction is the scientific approach to this problem, but to keep these patients on a diet is more theoretical than practical.

Nathan J. Frenn, M. D., Bark River, Mich.

Answer.—Amphetamine (benzedrine) sulfate and its dextrorotatory component dexedrine sulfate have been widely advocated in the treatment of obesity, since they curb the patient's appetite and maintain his feeling of well being despite a low caloric intake. However, as soon as the drugs are withdrawn the appetite returns in full and, unless a new food pattern has been established, the patient generally is unwilling to adhere to his former diet. There is also danger of habit formation, especially since the type of patient who is unable to restrain his appetite by his own will power will be one prone to habituation. Disagreeable side effects of a minor nature include insomnia, anxiety and palpitation.

THE MEDICAL SEQUELAE OF THE ATOMIC BOMB EXPLOSION

GEORGE V. LeROY, M.D.
Chicago

The Army and Navy medical missions which investigated the results of the explosion of the atomic bombs in Hiroshima and Nagasaki, Japan, studied many aspects of the situation. In this article it will be impossible to review all the studies that were made; only two major subjects will be considered. The two most impressive features of the new type of bomb are: (1) the tremendous toll of casualties and (2) the syndrome of injury due to large amounts of gamma radiation.

In the bombed cities the Air Raid Defense authorities and the surviving members of the medical profession were confronted with an extremely large relief and rescue problem. The magnitude of their task is indicated by the following estimates (table 1):

Table 1.—*Atomic Bomb Casualties*

	Hiroshima	Nagasaki
Population	300,000	200,000
Dead	80,000	40,000
Injured	40,000	25,000
Patients in need of immediate care	85,000	50,000

Of the total number of casualties, 120,000 in Hiroshima and 65,000 in Nagasaki, not all were in need of immediate medical care. In each city about one sixth of the total number of casualties were killed instantly or died under circumstances in which no help was possible. They were burned to death by the direct heat of the bomb, were crushed under demolished buildings or trapped in burning débris. A somewhat smaller group, perhaps one seventh of the total number of casualties, escaped both mechanical injuries and burns but received a dose of gamma rays sufficient to make them become sick one to five weeks later. On the basis of these rough estimates, it can be said that approximately 85,000 persons in Hiroshima and 50,000 in Nagasaki required medical care on the day of the bombing.

The type of injuries that required treatment can be appreciated readily from a brief review of the characteristic products of the explosion of an atomic bomb. At the instant of their detonation high above the ground these bombs generated an incredible amount of energy, of four main kinds: mechanical, heat, light and ionizing radiation (alpha, beta and gamma rays and neutrons). There was some variation in the length of time that each form of energy was effective in the production of damage and casualties; but in general the duration of time was of the order of 1 second (table 2).

The mechanical energy produced was in the form of an air blast, or concussion, sufficiently strong to crush reinforced concrete structures directly beneath the bomb; to wreck steel-framed factories at distances as great as 4,700 feet (1.4 kilometers) from the center of the effect; and to demolish Japanese type wooden houses as far from the center as 8,000 feet (2.4 kilometers). In each of the bombed cities practically every building was damaged in some way; and windows were shattered and roof tiles blown off as far as 3.5 miles (5.6 kilometers) from the explosion.

The heat at the center of the exploding bomb has been described in the newspapers as greater than that in the center of the sun. No reasonable estimate of the actual temperature of the reaction has been released officially, but it was almost unbelievably great, judging by the effects. During the fraction of a second that it lasted, inflammable objects were scorched or set afire as far from the source as 11,000 feet (3.3 kilometers). Practically every person who was in any position in a line of sight relation to the flaming airburst sustained burns of the exposed parts of the body that faced the blast. The burn was of the flash type, so that almost any object or material that happened to be located between the source of heat and the victim protected parts that were under cover or in the shadow (fig. 1). Close to the center, however, the heat was so intense that burns occurred under clothing. An interesting relation to the color of such clothing was seen, and the skin under dark material was burned more severely than that under white cloth. Bizarre designs were produced on the skin of patients whose clothing was of patterned material. People received flash burns serious enough to warrant treatment at distances as far from the center of the explosion as 13,000 feet, or 2.5 miles (3 kilometers).

Table 2.—*Casualty-Producing Agents Resulting from Explosive Nuclear Fission in an Atomic Bomb*

1	Mechanical energy "blast"
2	Heat
3	Light (visible, infra-red and ultraviolet)
4	Ionizing radiation (alpha, beta and gamma rays) and neutrons

The bright light that accompanied the explosion has been described as many times more intense than that of the sun. It may be thought of as comparable to sunlight concentrated by a "burning glass," and in this

---

Read before the Section on Internal Medicine at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 4, 1946.

Member, Joint Commission for the Investigation of the Effects of the Atomic Bomb in Japan. Chief of Division, Manhattan Department, University of Rochester.

This article is an abstract of a report submitted to the Surgeon General of the United States Army. The preparation of the report was the joint responsibility of Drs. Ashley W. Oughterson, New York; Shields Warren, Boston; Averill A. Liebow, New Haven, Conn.; E. Cuyler Hammond, New York; Henry L. Barnett, New York, and George V. LeRoy. Any opinions expressed are not necessarily those of all the colleagues, to whom, however, I am indebted for the use of the material.

sense it increased the amount of heat which caused the flash burns. Ultraviolet rays formed a part of the emission and caused typical conjunctivitis in some of the victims.

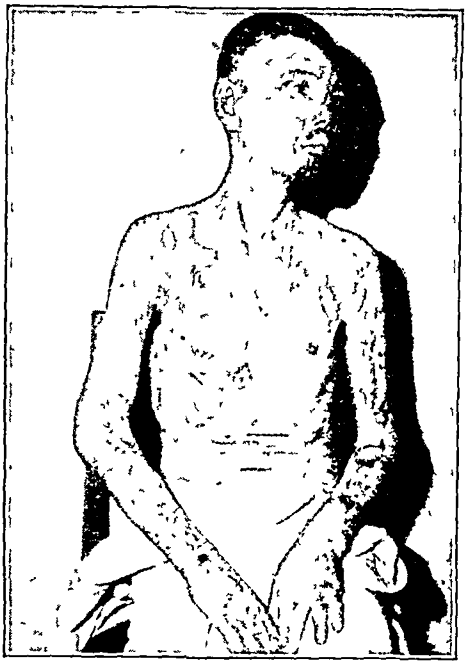

Fig. 1.—Example of extensive flash burn, some of which occurred under clothing Note the sparing of the eyelids and the anterior surface of the neck.

Ionizing radiation, consisting principally of gamma rays harder than those produced by any electrical apparatus known, were *emitted in amounts which can only* be guessed. Alpha rays, beta rays and neutrons were also produced, but the relation of these to the production of casualties is not at all clear.

With this knowledge of the products of the complex reactions that accompanied the splitting of the nuclei of atoms of uranium 235 and plutonium 239, it is possible to make a reasonable prediction of the sort of injuries that the victims of the bomb would have. In the confusion that followed the bombing few clinical records were kept in the aid stations, but enough information has been collected to permit the following estimate of the several types of injury (table 3):

Table 3.—*Classification of Injuries Due to the Atomic Bomb*

Wounds	70%
Burns	65 to 85%
Radiation injury	More than 30%

Data obtained from one large military hospital provided an approximate breakdown of the major types of wounds (table 4):

Table 4.—*Classification of the Major Types of Wounds*

Fractures	11%
Laceration, mainly due to fragments of glass	37%
Contusions	52%

(Source Ninoshima Hospital, Hiroshima)

These injuries resembled those that would be seen after hurricanes, earthquakes and to some extent after ordinary air raids. There were few blast injuries of the sort caused by high explosive bombs, however. Traumatic amputations, evisceration and general disintegration was infrequent. Few persons with extensive third degree burns lived long enough to receive medical attention, so that about 90 per cent of the burned patients in the aid stations and hospitals exhibited second degree burns. Less than 5 per cent of the burns were caused by the fires in damaged buildings and among the débris. The majority differed from ordinary flash burns only in the fact that the burned areas were darker in color than is usual.

The one unique type of injury caused by the atomic bomb was the syndrome due to gamma radiation—or simply radiation injury. It is not possible to state the precise dosage of gamma rays that any person or group of persons received in either Japanese city. It is equally difficult to estimate the amount of irradiation on the basis of the symptomatology because of the scarcity of information on the effect of large amounts of total body radiation in human beings. Guesses based on animal experiments are open to objections too numerous and too well recognized to be repeated here. The intensity of the gamma radiation emitted by the bombs decreased with the distance from the source in accordance with the law of the inverse square; and this is one of the two factors respecting dosage which can be discussed with certainty. The other is the well known ability of different types of matter to absorb gamma rays to a varying extent. Therefore, as might be expected, people inside heavily constructed buildings or in underground shelters were less severely affected than others at a comparable distance from the source who were in the open or in wooden structures. The amount of earth, brick or concrete necessary to give total protection from the gamma radiation of an atomic bomb at various distances is being studied intensively at present.

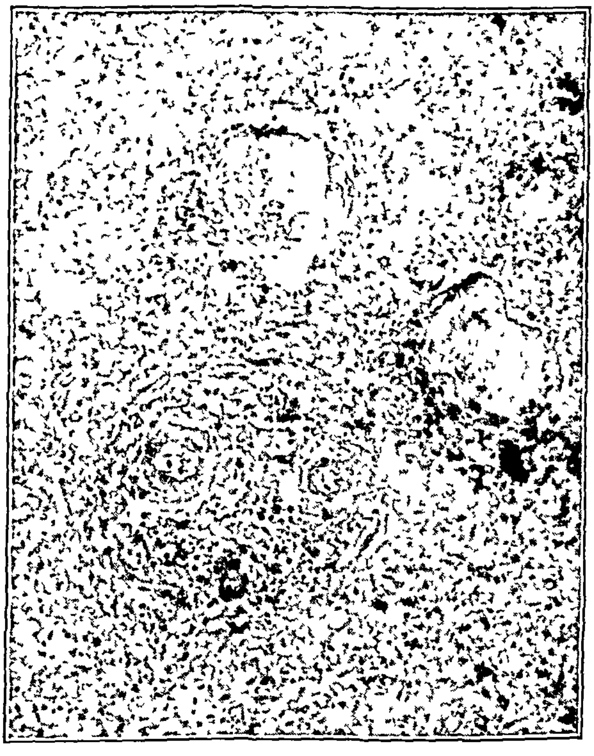

Fig 2—Spleen of man aged 24 who died five days after exposure to the atomic bomb. The field shows disappearance of lymphocytes from malpighian corpuscles, cytolysis of lymphocytes and fibrinoid changes in subendothelial portion of central artery, × 200

It was difficult to obtain precise information about the early symptoms of patients with radiation injury. It appeared that the majority experienced nausea and vomiting several hours after the bombing and that the symptoms were of rather brief duration. The course of the individual patient after that time depended mainly on the amount of radiation that he had received. Because of the complications in the clinical picture caused by burns and wounds, the description of the syndrome of radiation injury which follows is based largely on a study of patients with no other type of trauma.

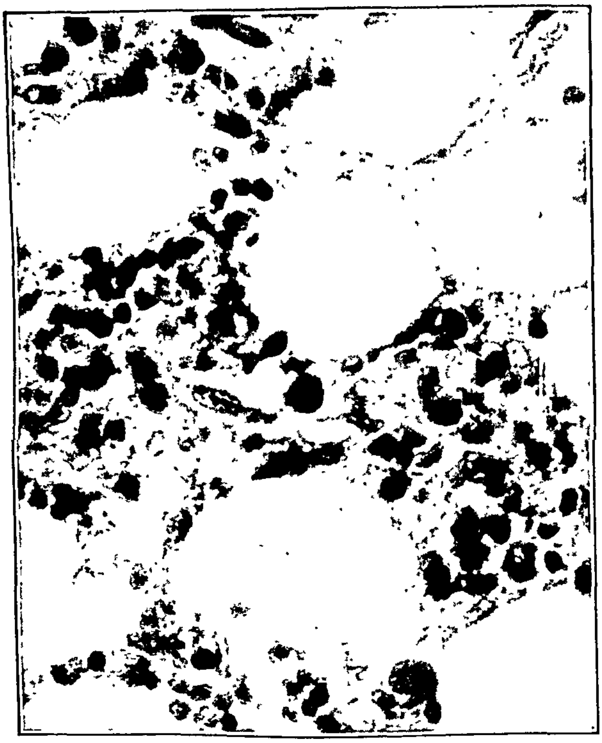

Fig. 3.—Bone marrow of man aged 39 who died seven days after bombing. The section shows a proliferation of reticuloendothelium and many plasma cells and lymphocytes. There are a few normoblasts remaining; × 650.

In those who received the largest doses of gamma rays, symptoms of fever and diarrhea were usually present on the day after the bombing (table 5 *A*). Purpura appeared approximately four to seven days later; the patient failed rapidly and died suddenly. Examination of the blood showed a pronounced reduction or a total lack of leukocytes and blood platelets. The urine was said to have been red in some cases, but few reliable reports were found. At autopsy[1] the observations were those of a moderate purpura hemorrhagica with widespread petechiae and a hemorrhagic erosion of the mucosa of the gastrointestinal tract.

Table 5.—*Onset of Symptoms of Radiation Injury*

	A Most Severe	B Severe	C Moderately Severe
Vomiting	Day of bombing	Day of bombing	Day of bombing
Fever	2-7 days	14-28 days	
Diarrhea	2-7 days	4-21 days	14-35 days
Leukopenia	2-7 days	7-28 days	7-28 days
Purpura	4-7 days	14-28 days	
Epilation	....	7-28 days	14-35 days
Mucous membrane ulceration	....	14-28 days	14-28 days
Anemia	....	7-28 days	10-35 days
Death	4-10 days	10-42 days	30-90 days

In one group of autopsies in this early stage, subarachnoid hemorrhage was found in 60 per cent of the patients. The bone marrow was pale, and the spleen and lymph nodes were small. Sections of spleen (fig. 2) and marrow (fig. 3) from typical cases are presented. Briefly, the important feature of these tissues is the disappearance of normal lymphocytes and marrow cells, so that only the stroma and the framework of the organs remain. There is evidence even at this early stage of a beginning of regeneration as seen in the proliferation of the reticulum. The general pattern of the observations in these cases resembles closely that described by Shouse, Warren, and Whipple[2] in dogs receiving large single doses of roentgen rays.

In the period between seven and twenty-eight days after the explosion of the atomic bomb symptoms developed in the majority of those affected by gamma radiation. The syndrome which appeared at this time was manifested by epilation, gastrointestinal disturbances (of which intractable diarrhea was the most frequent), purpura, fever, leukopenia and anemia (table 5 *B*). Associated with these primary phenomena were any of the complications which might be expected. Laryngitis, pharyngitis, tonsillitis and gingivitis developed in most of the patients. In the more severely afflicted these lesions, as well as lesions in the trachea, the bowel and the female genitalia, became progressive and severe necrotic ulcerations. This process differed in no way from that seen in agranulocytic angina from any cause. Petechia and purpura appeared in the skins of almost all the patients, and with the advent of the hemorrhagic tendency, epistaxis, melena, metrorrhagia and hematuria were regularly observed. Epilation (fig. 4) involved chiefly the scalp and was quite characteristic in appearance. The hairs of the crown fell out first, so that many of the victims appeared to have a monk's tonsure. The loss of hair was complete in only a few patients, and in the majority it began to grow again within two or three months' time. Epilation of other hairy parts of the body was infrequent. Laboratory studies at this time showed little that was abnormal except in the examination of the blood and bone marrow. Leukopenia was universal in patients with radiation injury when counts were made at an appropriate time. Values as low as 100 white blood cells per cubic

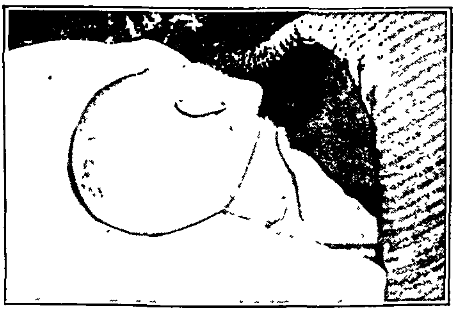

Fig. 4.—Example of epilation in a woman, showing almost total alopecia. The photo was made in October, twelve weeks after the bombing.

---

[1] Protocols and complete descriptions of all the autopsy and clinical material obtained in Japan will be described in the Report of the Joint Commission for the Investigation of the Effects of the Atomic Bomb in Japan. To be published.

[2] Shouse, S. S.; Warren, S. L., and Whipple, G. H.: II. Aplasia of Marrow and Fatal Intoxication in Dogs Produced by Roentgen Radiation of All Bones, J. Exper. Med. 53: 421-445, 1931.

millimeter were reported, and the majority of the heavily irradiated patients had white blood cell counts below 1,500. Recovery appears to have been rare among patients whose white cell count was less than 600 per cubic millimeter. Examination of stained blood films at that time revealed mainly lymphocytes. Anemia was present in all such patients and became progressively more pronounced for a period of one to two weeks after the maximum depletion of the white count was observed. The purpura and the hemorrhagic tendency increased the anemia, and patients in whom this was a prominent feature of the syndrome did poorly. Associated with the leukopenia and the agranulocytic type of ulceration, there occurred overwhelming infections, many of which became septicemias. This condition and pneumonia seem to have been the chief causes of death in this stage. The mortality rate for this form of the syndrome of radiation injury is not known. Some Japanese physicians said that it was 100 per cent; but it is more likely that a fair estimate would be between 50 and 75 per cent. In small groups of persons treated in a university hospital the mortality rate was about 33 per cent. When this type of radiation injury developed in a burned or wounded patient, however, the prognosis was much worse because of the increased suppuration of the wounds. Sections of representative tissues from patients who died at this time are illustrated. The bone marrow (fig. 5), the spleen (fig. 6), the testis (fig. 7) and a section of burned skin (fig. 8) with no polymorphonuclear reaction are presented. The failure of spermatogenesis was constant in patients who were exposed to sufficient gamma radiation to produce clinical symptoms, and the extent of the process is evident from the illustration.

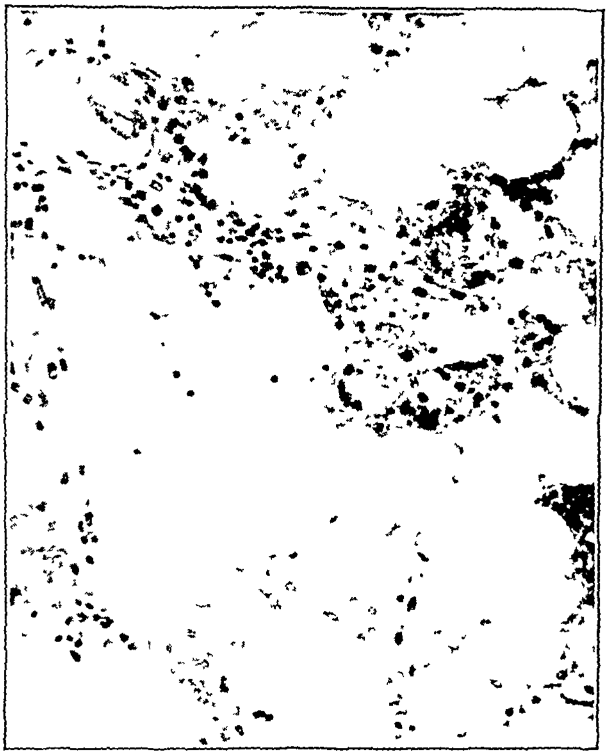

Fig 5—Bone marrow of man aged 29 who died twenty nine days after the bombing The section shows hypoplasia, a necrotic area and bacteria. The majority of the cells are reticulum cells, plasma cells and lymphocytes, × 230

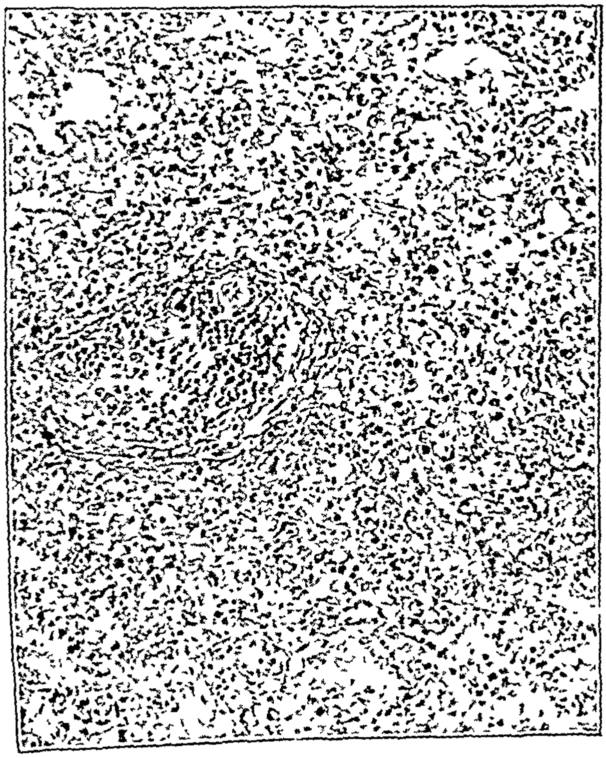

Fig. 6—Spleen of woman aged 35 who died nineteen days after the bombing. The section shows atrophy of the lymphoid tissue, with karyolysis of some of the cells in the vicinity of the central arteriole The arterioles show a deposition of hyalin like material beneath the endothelium; × 160

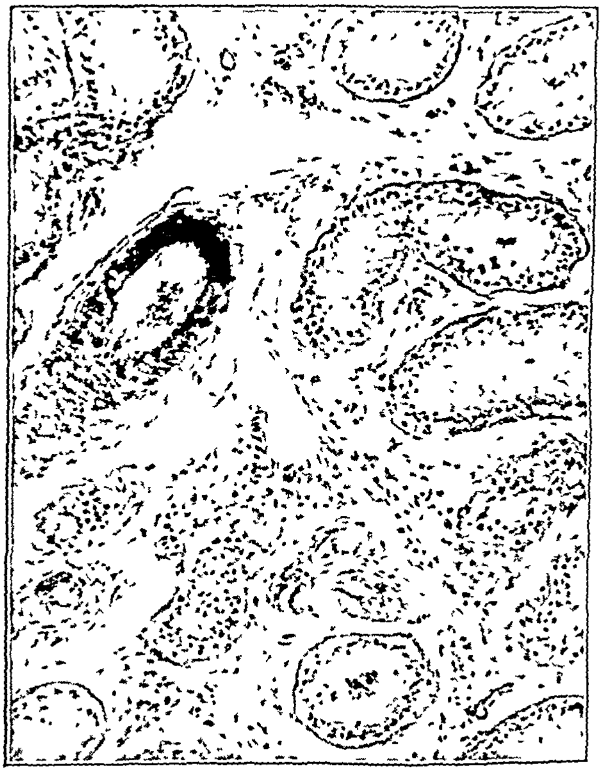

Fig 7—Testis of man aged 22 who died twenty six days after the bombing The section shows necrotic remnants of germinal epithelium and its derivatives in the lumens of tubules, edema of interstitial tissues, and hyaline subendothelial changes in small blood vessels, × 125

A less severe form of the syndrome of radiation injury occurred. In these patients epilation, if it occurred at all, was observed during the third to fifth week after the bombing (table 5 C). The constitutional symptoms of fever, gastrointestinal disturbances and prostration were conspicuously less serious. The other characteristic clinical phenomena in this group were weakness, malaise, diarrhea and mild inflammation of the mouth, gums and throat. Examination of the blood at an appropriate time revealed leukopenia, but white blood cell counts were seldom lower than 1,500 per cubic millimeter. The number of blood platelets was reduced, and anemia was a constant and often progressive feature. Frank ulceration of the inflamed mucous membrane was infrequent and tended to be transitory. Petechia appeared in rather small numbers of patients, and the hemorrhagic tendency was never extreme. Anemia was the most conspicuous element in the symptomatology; some of these patients never recovered but died two to four months later with an aplastic anemia. Sections from such a patient show poorly regenerating marrow (fig. 9) and testicular tissue (fig. 10).

The most important pathologic changes in the tissues may be summarized briefly. The bone marrow was badly damaged, and there was an almost complete disappearance of all cells of the myelopoietic and erythropoietic series. However, in all but the most severely irradiated patients regeneration of the bone marrow was evident within seven to ten days after the injury. The type of tissue which regenerated varied considerably and frequently after three or four weeks the marrow appeared to be producing mainly macrophages, plasma cells and lymphocytes, with only insignificant numbers of definitive cells. In other cases a well-established myeloid and erythroid hyperplasia was evident at this time, and in tissues obtained later this process was often spectacular. The lymphatic organs all were badly damaged, and material from the earliest cases contains few or no lymphocytes in the nodes, the spleen and the thymus. Recovery of these tissues was evident after a few weeks, as a rule, but they never displayed the degree of hyperplasia that the marrow did. In many patients who died several months after irradiation, the lymphatic tissues still contained only a fraction of the usual number of adult-type lymphocytes. The testes

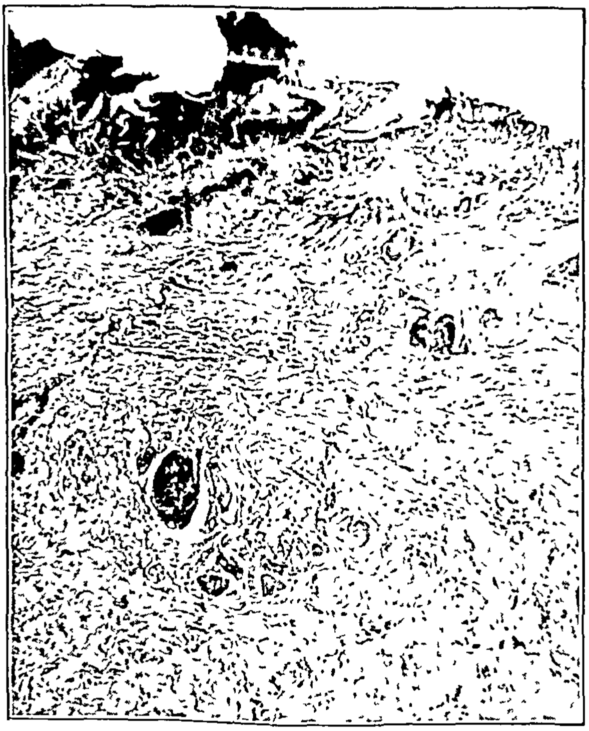

Fig. 8.—Skin of man aged 39 who died seven days after the bombing. The section shows burned skin, with necrosis of epidermis and outer layers of the dermis. Masses of bacteria are present, but there is no leukocytic infiltration whatever; × 50.

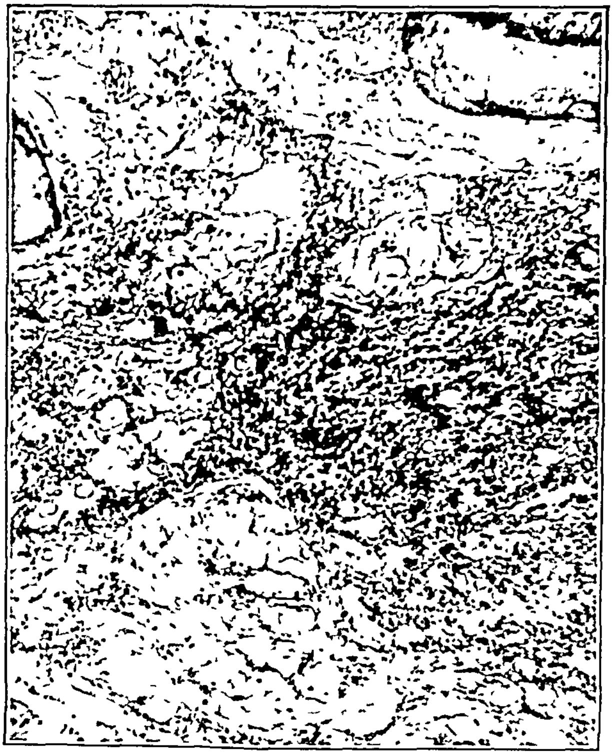

Fig. 9.—Bone marrow of man aged 31 who died fourteen weeks after the bombing, of bronchiectasis. The section shows gelatinous marrow from the rib, in which there is a large focus of regenerating cells replacing the fat; × 115.

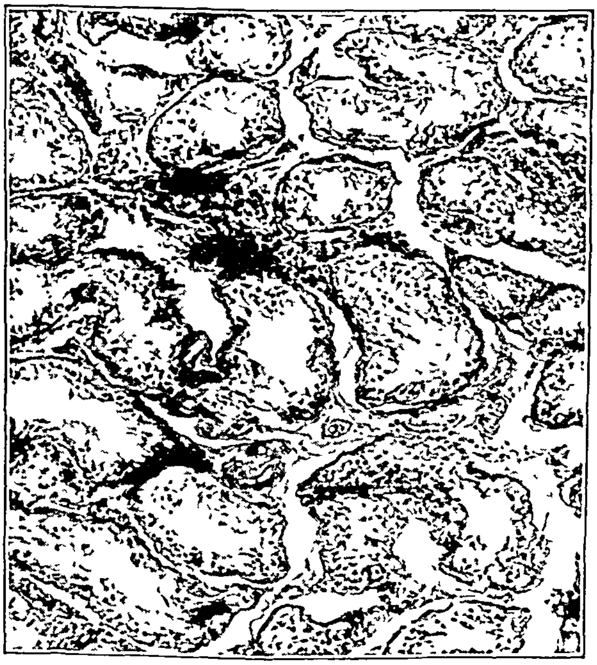

Fig. 10.—Testis of man aged 31 who died fourteen weeks after the bombing, of bronchiectasis. The section shows complete cessation of spermatogenesis. The tubules whose basement membranes have not become thickened are lined with cells of Sertoli. The interstitial tissues are not hyperplastic; × 115.

were affected in the majority of men who received enough gamma radiation to cause symptoms. Spermatozoa were absent from the tubules, and most of the spermatogenic tissue was replaced by proliferating cells of Sertoli. As a corollary of this damage, changes of the type seen in castrated persons were apparent in the pituitary gland. The tissues of the female reproductive system were affected to a much smaller extent. The changes in the skin and in the hair follicles were prominent and resembled the type seen after treatment with roentgen rays.

The therapeutic problems that were presented by these patients with severe injury due to exposure to large doses of gamma radiation can be summarized quickly: The two major phenomena which endangered life were the gastrointestinal disturbances and the destruction of the hematopoietic tissues. The intense diarrhea and vomiting and the ulceration that occurred throughout the bowel created a serious situation. There is no doubt that many patients died from this cause alone with dehydration and acidosis. The damage to the bone marrow was even more serious, although it appears from histologic studies that regeneration of a sort commenced soon after the injury. Severe leukopenia which persisted for a period of one to three weeks was certain to facilitate the development of overwhelming infections in any part of the body. The inability of the leukopenic organism to localize such infections could result in the development of septicemia. The hemorrhagic state which accompanied the thrombocytopenia was capable of causing exsanguination from the ulcerated mucous membranes or from wounds as well as fatal hemorrhages in the central nervous system, the myocardium or the adrenal glands.

The proper objectives in the treatment of patients who have been exposed to the amount of gamma radiation emitted by an exploding atomic bomb are quite clear and can be stated simply (table 6):

TABLE 6.—*Therapeutic Objectives in Management of Patients with Radiation Injury*

1 Maintain fluid and acid-base balance
2 Control infectious processes
3 Combat hemorrhagic tendency
4 Correct the anemia

It does not seem unreasonable to believe that in the hospitals of the western world where plasma, electrolyte solutions, whole blood and penicillin are available in adequate amounts, a much lower mortality rate could be achieved than was observed in Japan. How satisfactory the thoroughly modern treatment of the syndrome of radiation injury might be is difficult to predict.

30 North Michigan Avenue.

ABSTRACT OF DISCUSSION

DR. VERNE R. MASON, Los Angeles: I should like to call attention to certain details about which Dr. LeRoy did not have time to elaborate. First, the changes in the bone marrow are not constant from day to day or week to week but represent a dynamic process that is going on. Dr. LeRoy has a large number of slides and a large amount of statistical material and, when he gets these all together, will make an amazing picture of what actually goes on in the bone marrow of persons who have had very large doses of gamma-ray radiation to the total body. Another factor may be of interest. In Hiroshima the last patient who died from severe leukopenia died on September 24. The bomb exploded on August 6. The early mortality, therefore, was of high degree and the total mortality became very large by September 24. As far as we could determine from very brief Japanese records of patients studied by Japanese doctors, there was a large number of patients who died in the bombed area soon after the explosion who showed no changes of the blood but died with fever, diarrhea and shock as the chief symptoms. It is our opinion at present that these persons died an acute death produced by an overwhelming dose of gamma radiation. I believe at the moment that Dr. LeRoy and Dr. Liebow have not completed their studies on this particular group of patients, on whom we have records of a small number of autopsies. As time went on, many who undoubtedly had developed leukopenic states earlier survived because they were fortunate not to develop the type of infection frequently seen in terminal stages of leukopenic states. Thus they may have survived the early phase of leukopenia and then later we saw a decreasing total mortality. But some of them ultimately died of an irreversible change in the bone marrow which led to an aplastic anemia. When the studies are completed (this is only a guess on my part) the time in which the leukopenic state developed in many of these patients will, I believe, practically correspond to the known life span of the white blood cell. Those who died of aplastic anemia later lived a period of time which will about correspond to the known life of the red blood cell. That, I think, is one of the important phases that will be brought out when these reports are completed.

POLIOMYELITIS

Neuropathologic Observations in Relation to Motor Symptoms

DAVID BODIAN, M.D.
Baltimore

There are few diseases which illustrate as well as poliomyelitis the importance of a quantitative point of view in evaluation of the variegated clinical patterns. In this infection the subclinical case grades into the clinical case and the nonparalytic into the paralytic with no sharp qualitative separations and with correspondingly wide variations of intensity of pathologic change in nervous tissues. Death itself may come as the result of an unusually intense involvement of localized vital brainstem centers, which are to some extent involved even in mild cases, or may follow widespread damage to many important centers without overwhelming any one of them. In such cases it is obviously impossible to say which straw it was which broke the camel's back. In the course of study of the pathologic material from 24 human cases, 13 of them previously described in detail,[1] it became increasingly clear that the use of pathologic material from such fatal cases in the correlation of symptomatologic data with lesions is extremely dangerous. One reason for this is the simple fact that death in poliomyelitis seldom occurs except as the result of such widespread and severe damage that important details are masked. Another reason is the uncertainty of judging whether lesions are sufficiently severe to significantly alter normal function. Neverthe-

Aided by a grant from the National Foundation for Infantile Paralysis, Inc.

From the Poliomyelitis Research Center, Department of Epidemiology, Johns Hopkins University School of Hygiene and Public Health.

Part of this material was presented at the Conference on the Structure and Function of Nerve and Muscle in Relationship to Infantile Paralysis at the State University of Iowa College of Medicine, Sept. 14, 1946.

The author is greatly indebted to several persons for their assistance in obtaining the human pathologic material. Cases 1 to 21 have been previously described,[1] and their sources have been acknowledged. Cases 29 to 40 occurred in Baltimore during the outbreak of 1944. Clinical data was made available by the generous cooperation of Dr. Margaret H. D. Smith and the members of the staff of the Sydenham Hospital; pathologic material was obtained with the kind assistance of Dr. Arnold Rich and the members of the staff of the Pathology Department of the Johns Hopkins Hospital.

[1] Howe, H. A., and Bodian, D.: Neuropathological Evidence on the Portal of Entry Problem in Human Poliomyelitis, Bull. Johns Hopkins Hosp. 69: 183, 1941.

less, numerous clinical observers since the time of Strümpell[2] and Medin[3] have attempted to correlate the symptomatologic manifestations of human poliomyelitis with cerebral as well as with spinal lesions. Some, like Wickman,[4] who gave to the problem a wealth of accurate observation and keen insight, made important contributions which are still not fully appreciated by modern workers in this field. My own interest was aroused from the direction of neuropathology, since anybody with a knowledge of the rudiments of neurology who examines cerebral sections from poliomyelitis patients is almost certain to wonder what are the clinical concomitants of the extensive lesions in the brain. Of course, when the patient has had a right-sided facial paralysis one will find severe neuron destruction and inflammatory changes in the right facial nucleus, but when one looks beyond the primary motor centers the clinical-pathologic correlations are much more obscure and complex. Added to the theoretic difficulties are the practical ones. In many fatal cases the patient enters the hospital in severe respiratory distress and cannot be adequately examined. This results, for example, in the extremely obvious discrepancy between recorded clinical involvement of cranial nerve musculature and the pathologic observations in corresponding cranial nerve nuclei in many patients (table 1). Moreover, many are, or become, so severely paralyzed that other symptoms are masked. Despite this difficulty it was decided that it might be instructive to study human material in the light of experience obtained with experimental material in order to compare the human disease with controlled experimental cases, and to determine how far it is possible to use human material for specific problems of pathogenesis and symptom analysis.

Three features of the pathologic picture of poliomyelitis must be clearly understood before one can make a satisfactory correlation of clinical symptoms with pathologic substrate. The first is the fact that all the evidence available shows conclusively that every case of poliomyelitis, human or experimental, exhibits lesions of the brain.[1] In the experimental animal this includes nonparalytic and abortive cases as well as paralytic cases. As far as the pathologist is concerned, all cases of poliomyelitis are encephalitic. The second fact is that in human poliomyelitis, as well as in most experimental cases, some parts of the brain seldom if ever are affected. These include primarily the entire cerebral cortex, except for the motor area, the corpus striatum except for the globus pallidus and the cerebellar cortex except for the vermis. In other words, the brain stem, as far forward as the hypothalamus and thalamus, bears the brunt of the cerebral pathologic changes in poliomyelitis. The third important generality is that great variation occurs in the severity of pathologic involvement of most central nervous system centers, but the same centers are generally involved in greater or lesser degree in almost all cases. I should like to emphasize this last point by stating that 2 fatal cases in which the patients did not primarily die of poliomyelitic infection did not differ in any fundamental regard from other fatal cases with respect to distribution of lesions in the brain (cases 9 and 40).

THE ROLE OF BRAIN STEM CENTERS

Of those centers in the nervous system concerned with muscular function, the following commonly are involved to a greater or lesser degree in human and in experimental poliomyelitis: the motor cortex, the globus pallidus, the substantia nigra, the subthalamus, the red nucleus, the tegmentum of the midbrain, the cerebellum, the vestibular nuclei, the reticular formation of the pons and medulla oblongata, the motoneurons of the brain stem and spinal cord, the internuncial neurons in the intermediate and posterior columns of the spinal cord and the proprioceptive cells in sensory ganglions (table 1).

If all the motoneurons of the spinal cord were destroyed in every case of poliomyelitis, the problem would be simple. All the symptoms that might result from damage to these centers would be masked by the flaccid paralysis resulting from damage to one of them, the anterior column of the cord, which contains the lower motor neurons. It happens, however, that complete flaccid paralysis is infrequent as compared with the partial paralyses that result from irregular destruction of motoneurons in the cord. The problem, then, is to attempt to evaluate disturbances of function due to lesions of the upper motor neurons in a mixture of normal muscles and muscles weakened by lesions of the lower motor neurons. One can take as a point of departure in this problem two important facts which are clear from previously published work.

The first is that clumsiness, hyper-reflexia, spasticity and tremor of muscles have been demonstrated in the preparalytic stage of experimental poliomyelitis before virus or lesions could be demonstrated in the region of the spinal cord which corresponded to the affected muscles. Severe lesions, however, were always present at this time in centers of the brain stem in these cases.[5] A primary separation of the role of cerebral and of spinal cord centers in the production of motor symptoms can therefore be made from an analysis of experimental animals killed in the preparalytic period. It is interesting that Wickman mentioned the possibly analogous occurrence of increased patellar reflex in an otherwise normal leg in some cases involving paralysis of the arm.

The second fact is that experimental animals may have lesions in all the previously enumerated cerebral centers without manifesting any clinical evidence of muscular dysfunction. In fact, it has been shown that some animals with nonparalytic poliomyelitis do not have any lesions in the spinal cord but have a characteristic distribution of lesions in the brain.[6]

It is this last point which suggests an important further simplification of the problem. Apparently, severe destructive lesions are usually necessary to produce dysfunction at the clinical level, and one must therefore look for centers which are severely involved to locate the site of origin of clinical signs. The large margin of safety of some cerebral centers is a well known feature of central nervous system function.

With this point in mind, one can see that in experimental animals as well as in human beings, only a few centers in the brain are severely involved often enough to suggest that they regularly play an important role in the motor symptoms of poliomyelitis. These centers in the series of 24 human cases, along with those less severely involved, are arranged in table 2 in a frequency series to show more graphically their relative importance as sites of pathologic change.

It is obvious that in the brain the centers most frequently damaged severely are the vestibular nuclei, the roof nuclei of the cerebellum and the reticular formation. It is extremely interesting that these three centers are interconnected by vestibulocerebellar and fastigiobulbar tracts, and two of them, the vestibular nuclei and reticular formation, are connected with the spinal cord. It is possible that they should be grouped together as a functional entity and that they therefore may play a joint role in modifying voluntary motor function and in regulating postural tone.[7] Magoun, in fact, has demonstrated experimentally the role of the reticular formation in modifying spinal motor activity.[8] Severe lesions in one or all of these centers may therefore superimpose on muscles weakened by imperfect spinal innervation varying degrees of altered suprasegmental control, which clinically might appear as varying degrees of hypertonia or hypotonia, ataxia, tremor and weakness.

Fatal human cases manifest the destructive changes in these centers in maximal form. Experience with the larger range of material made possible by the use of experimental animals shows that in nonfatal cases one would not always expect the maximal effect. As a matter of fact, in some of the human cases in which there were no bulbar signs, and in which death was due to paralysis of respiratory muscles or to complications unrelated to the poliomyelitis infection, there was found a degree of involvement of brain centers comparable with that in mild paralytic or nonparalytic experimental cases. In 1 of these cases a boy aged 13 was recovering nicely from poliomyelitis when he succumbed to an attack of appendicitis fifteen days after the onset of his poliomyelitic infection. He had had muscular pain, a stiff neck and a stiff back early in the course of his disease, along with weakness of the arms. Unfortunately, he had not had a thorough neurologic examination before he died (case 9). In instances of this kind the only centers consistently showing severe damage have been the vestibular nuclei, especially Deiters' nucleus, and the reticular formation.

Table 2 is intended to show both the variation of intensity of pathologic damage in various centers and the frequency of occurrence of severe, moderate or mild degrees of damage in the series. Obviously, these grades of severity are subject to varying interpretation. The grade "severe" in any particular center indicates the greatest degree of damage in that center in my experience. In regard to the vestibular nuclei, cerebellar roof nuclei and the lower reticular formation, this term generally means destruction of at least 70 per cent of neurons. As a rule then, the severest damage occurs in the vestibular nuclei and in the reticular formation.

THE ROLE OF THE CEREBRAL CORTEX

Cortical lesions are seldom severe and are largely confined to the motor cortex (areas four and six of Brodmann). It is doubtful that they are sufficiently intense to produce clinical signs, except perhaps in rare instances. However, it is not unlikely that damage to centers such as the motor cortex, globus pallidus, substantia nigra, certain midbrain centers and even spinal ganglions, although usually not sufficient alone to produce obvious motor dysfunction, as in nonparalytic cases, may be important if added to severe changes in the centers which have been shown to be primarily involved.

It may also be concluded from the relatively slight involvement of the cerebral cortex in poliomyelitis that residual psychic effects as well as spastic phenomena cannot be the result of specific lesions in the cerebral cortex. Moreover, other so-called encephalitic symptoms, including stupor, disorientation and coma, which occurred in some of these patients, were not associated with heavier than usual reaction in the cerebral cortex but rather with a greater intensity of reaction in the brain stem, which sometimes led to the production of small focal softenings (cases 12, 29, 30, 31, 37 and 38). It is the fortunate sparing of most of the cerebral cortex which should remind physicians that the patient may be intellectually and emotionally involved in the frightening experience of loss of motor power. It is problematic whether the severe lesions sometimes found in the hypothalamus may contribute in some instances to emotional difficulties.

THE ROLE OF SPINAL CENTERS

In the spinal cord, as was to be expected, the severest lesions were always in the anterior columns. With severe involvement of the cord posterior and intermediate horns may also be heavily damaged, but such damage is more spotty in distribution than in the anterior horns, and the posterior and intermediate columns are never wiped out over whole segments as are the anterior columns at times. It is also to be expected, then, that when internuncial neurons are severely affected the neighboring anterior columns of the cord are so extremely damaged that flaccid paralysis is likely to be the only symptom referable to this region of the cord. The possibility remains, however, that internuncial neuron damage in the cord may contribute to the motor dysfunction of muscles not completely paralyzed. The intermediolateral, or sympathetic, cell columns are surprisingly little involved, but in 1 of the cases there was considerable destruction of cells in these columns. Similarly, Clarke's column was usually spared and was never extensively involved.

I have seen no evidence in this material, experimental or human, that edema may play a conspicuous role in the production of paralysis. Whenever a severe inflammatory response occurs in a cord segment, the cord in such an area may show swelling of the freshly cut surface. In my experience, however, an inflammatory response severe enough to produce massive exudate in the anterior gray columns usually occurs when most of the anterior horn cells are already destroyed by virus action. In such cases there can be no question

of possible recovery from paralysis, since all or most of the motoneurons are destroyed. Severe paralysis may occur, however, without evidence of edema and in some instances without vascular changes or severe leukocytic infiltration in the cord. Such cases are conclusive in demonstrating that the paralysis of poliomyelitis primarily depends on a direct action of the virus on the motoneurons rather than on primary circulatory or inflammatory phenomena, as has recently been reaffirmed by Nelson.[9] Experimental evidence, which was apparently ignored by this author,[9] has been abundantly available to demonstrate the selective action of the virus on nerve cells.[10]

Table 2.—*Twenty-Four Fatal Cases of Human Poliomyelitis*

Intensity of Pathologic Damage in Motor Centers of the Central Nervous System

	Severe	Moderate	Mild	Absent
Motor cortex	4	15	1	4

Lumbar cord	6	3	2	0

In experimental as in human cases anterior horn cells may be destroyed either in large groups or in scattered fashion. Destruction does not occur suddenly, as in sectioning of the nerves, but follows a mortality curve in the motoneuron population over a period of several days or longer. Atrophy in experimental animals is proportional to the number of motoneurons destroyed; in human beings, atrophy of disuse may be superimposed on denervation atrophy to a greater extent than in the always active monkeys. Paralysis is also largely proportional to motoneuron destruction, if one means by paralysis loss of power in a maximally stimulated muscle which has not been allowed to atrophy due to disuse. Paralysis of voluntary movement is another matter, and one which certainly may involve more than lower motoneuron dysfunction, as has already been indicated. It obviously may occur *without motoneuron destruction*: for example, in cases of cerebral injury, in extreme fatigue and in hysterical conditions. It is not always recognized that ordinary testing of the muscles, using Lovett's or similar grading methods, although useful, measures not the potential power of surviving motor units but rather the complex act of performance. Further, such grading is useless for quantitative analysis of the symptoms due to motoneuron lesions because it is not a true scale but an arbitrary scheme, which gives only the sequence of increasing quantities. But these quantities are unknown because no unit of quantity is defined. In monkeys it has been found that the best way to determine residual muscle power of surviving motor units after the acute stage of the disease is to stimulate motor nerves or motor points of the muscles involved. It would seem desirable that this be done in selected human subjects to compare potential muscular power with voluntary performance.

FACTORS IN THE RECOVERY OF MOTOR FUNCTION

Although any discussion of recovery factors must necessarily be speculative in part at this time, even a speculative analysis from the point of view of histopathologic study may be helpful in identifying the parts of the neuromotor apparatus which must be considered. Table 3 summarizes the role of these parts and the period of time during which recovery in each is probably most prominent. As already stated, the cerebral cortex is so little affected by the disease process that there is every reason to suppose that the patient can rapidly begin to relearn patterns of motor activity which formerly were smoothly and subconsciously regulated by now severely damaged brain stem mechanisms. It is generally agreed that motor reeducation is of the greatest importance in assisting recovery, and in this respect the cerebral cortex must play the dominant role.

Most of the brain stem centers concerned with motor function are damaged in varying degree in poliomyelitis, yet an evaluation of recovery from this damage must be phrased in exceedingly general terms until the precise contribution of each center in motor functions is better understood. It is difficult to believe that the damage to the brain stem does not affect motor performance even in some cases of mild paralysis, since such instances in experimental animals (6) and in the 2 cases of human poliomyelitis in which the patients died of other causes after fifteen and seventeen days (cases 9 and 40) showed considerable neuron destruction and infiltrative lesions in some brain stem centers, especially the vestibular nuclei and reticular formation. Recovery from such lesions should result from at least two processes: first, the recovery of neurons not damaged sufficiently to be destroyed and second, the rerouting of neuron-chain discharge pathways from interrupted primary paths to secondary alternative paths. The first process is probably completed in about one

Table 3.—*Factors in the Recovery of Motor Function in Poliomyelitis*

Part of Neuromotor System	Recovery Process	Period of Disease
Cerebral cortex	Relearning of complex neuromotor patterns	Entire convalescent period
Brain stem	1. Recovery of damaged neurons	First 4 to 6 wks.
	2. Rerouting of neuron discharge pathways	First 6 mos. or longer (?)
Spinal cord	1. Recovery of injured motoneurons	First 4 to 6 wks.
	2. Recovery of internuncial pathways	First 6 mos. or longer (?)
Peripheral nerve	Compensatory branching of surviving motor axons (?)[11]	Subacute and early convalescent period (?)
Muscle	Compensatory hypertrophy	Probably subacute and early convalescent periods

month, as is the case in the spinal cord; the second process probably is of longer duration, since it is a part of the relearning process.

In further assessing the pathologic factors which underlie the paralysis in poliomyelitis, it is important to note that positive evidence is now available for the well known supposition that reversible changes may occur in spinal motoneurons in the acute stage of the disease. In experimental and in human material intranuclear inclusions may be found in anterior horn cells of otherwise normal appearance in the subacute and convalescent periods. Since such inclusions are an accompaniment of severe cytoplasmic chromatolysis in the acute stage, it follows that these cells are recovering. This means that one component of muscular weakness in the acute stage may be a partial and temporary loss of function of some motor units, as contrasted with the commoner occurrence of irreversible loss of function of a varying number of denervated muscle fibers due to motoneuron destruction. The reversible changes in motoneuron cell bodies in experimental material are negligible after the first month or so (data to be published in detail separately). After this time recovery of function in muscles must largely depend on other factors (table 3). In the human material of this present study the entire spinal cord was available in 1 patient who survived longer than two weeks (case 40). In this case, in which destruction of anterior horn cells was extensive throughout all levels, over 90 per cent of the surviving motoneurons were normal in appearance and most of the others were only moderately chromatolytic.

Since lesions, sometimes severe, are found in the posterior and intermediate horns of the spinal cord as well as in the spinal ganglions, it is possible that spinal internuncial discharge pathways and reflex pathways may be injured sufficiently to contribute to motor dysfunction. Recovery of such mechanisms probably follows a course similar to that in the centers of the brain stem, since the two are intimately connected by ascending and descending pathways.

Experimental evidence, which has been recently presented,[11] that intramuscular branching of intact nerve fibers in partially denervated rabbit and rat muscles may supply some of the denervated muscle fibers has introduced a new possibility among the factors concerned in the recovery from poliomyelitis. However, whether this type of recovery actually occurs in poliomyelitis remains to be determined. Since chromatolysis of anterior horn cells, an excellent indicator of axon interruption, is not seen in significant amount after about one month following the onset of poliomyelitis, it seems likely that any regenerative phenomena involving the growth of axons or axon branches must occur far distal to the cell body, at least in the intramuscular portion of the nerve.

As far as the recovery of function due to intrinsic changes in muscle is concerned, compensatory hypertrophy probably plays a significant role. As in the case of the other recovery factors mentioned, however, its relative importance is difficult to assess because of the variety of factors involved in the recovery process.

In conclusion, it should be apparent that many of the symptoms of poliomyelitic muscular dysfunction mentioned in this paper were not recorded in the histories of the fatal cases studied histopathologically (table 1). The reasons for this have been discussed in the opening paragraphs, and the dangers of correlating symptoms in nonfatal cases with lesions in fatal cases should be manifest. Symptoms which were recorded in most of the cases, however, were muscular pain, stiff neck and stiff back. This material can offer no more than a confirmation of earlier observations of lesions of varying degrees of severity in meninges, spinal ganglions and posterior columns of the spinal cord to account conceivably for these symptoms. In view of the rather slight involvement of these areas in many cases, such an interpretation seems too facile. The common symptoms of stiffness of the neck and back are usually interpreted as being due to meningeal irritation. It is possible to speculate that the stiffness of neck and back may also be the result of the same disturbances of the brain stem which give rise to other phenomena of spasticity in poliomyelitis. This is suggested by the frequently occurring pattern of hypertonia in postural muscles in human poliomyelitis. The origin of this pattern should be explored experimentally. The origin of muscular pain in poliomyelitis and its possible relationship to spasticity of the muscles also requires further exploration.

It should be manifest that this account has been somewhat simplified in the interest of brevity and provocation. A more detailed analysis of available autopsy material has seemed to be unprofitable until such time as more complete pathologic studies in this disease and more complete studies of normal neuromotor mechanisms are available. To one who has examined material from many dozens of monkeys and chimpanzees in all stages and degrees of severity of clinical poliomyelitis, the paramount importance of variability of intensity of pathologic change is so apparent that almost any attempt at a statement of general principles seems an oversimplification of the problem at present. In addition to the variation of intensity of pathologic change which occurs in different persons one can definitely add the variation due to different strains of virus. One group of monkeys inoculated with a given dose of strain A will show mild degrees of paralysis and no signs of spasticity. Another group inoculated with the same dose of strain B will exhibit severe spasticity in the majority of cases and subsequent severe paralysis. Variations of this sort must be expected in different epidemics.

SUMMARY

1. An extensive histopathologic survey of 24 fatal human cases of poliomyelitis confirms older accounts in showing that all victims of poliomyelitis have lesions in the brain and that the severest lesions occur in the brain stem rather than in the cerebral cortex. Moreover, great variation occurs in the severity of pathologic involvement of most centers of the central nervous system, but the same centers are generally involved in greater or lesser degree in almost all cases.

2. Motor centers involved to a greater or less degree in human and in experimental poliomyelitis are: motor cortex, globus pallidus, substantia nigra, subthalamus, midbrain tegmentum, cerebellum, vestibular nuclei, reticular formation of pons and medulla oblongata, motoneurons of cranial and spinal nerves, internuncial neurons in intermediate and posterior columns of cord and proprioceptive cells in sensory ganglions.

3. Lesions in most of these centers are characterized by wide variations of intensity both in human and in experimental poliomyelitis. Lesions of moderate inten-

sity occur in most of these centers in symptomless or nonparalytic experimental infections.

4. Severe destructive lesions occur in the vestibular nuclei, the reticular formation and the roof nuclei of the cerebellum in most fatal human cases and in many paralytic experimental infections. These are the only brain centers which regularly contain extremely severe lesions. Since it has been shown[5] that spasticity, tremor and hyper-reflexia of leg muscles can occur in the preparalytic stage of experimental poliomyelitis in the absence of virus or lesions in the lumbar spinal cord, it is suggested that lesions in these centers of the brain stem may be primarily responsible for these symptoms.

5. The possibility is not excluded that the less regularly severe lesions in centers like the motor cortex, globus pallidus, substantia nigra, certain midbrain centers, internuncial neurons in the spinal cord and even spinal ganglions may contribute to motor dysfunction other than lower motor neuron weakness.

6. Histopathologic observations indicate that most nerve cells either are destroyed during the acute stage of a poliomyelitis infection or largely recover their normal appearance in about one month or less. Such recovery of reversibly injured lower motor neurons may be a primary factor in the early restoration of muscle function.

EXTRANEURAL GROWTH OF POLIOMYELITIS VIRUS

Its Significance Relative to Possible Methods of Prevention

C. A. EVANS, M D, Ph.D.
Seattle
and
R. G. GREEN, M D.
Minneapolis

Attempts to demonstrate the growth of poliomyelitis virus in cells other than neurons have repeatedly failed[1] (1936). As a result the opinion has been prevalent that in the human body growth of the virus is limited to nerve cells. That this conclusion is premature and may well be wrong is indicated by a number of well established facts relative to (1) the amount of poliomyelitis virus in human feces; (2) the prolonged period of excretion of virus in feces; (3) the usually short period of growth of virus in the central nervous system of experimental animals, and (4) the frequent intestinal infection without apparent neurologic infection seen in work with Theiler's virus in mice.

The information available in regard to the amounts of poliomyelitis virus in feces casts considerable doubt on the idea that this virus grows only in nerve tissue. In tests with pooled fecal specimens from 25 patients, we have found sufficient virus in 5 mg. of feces to infect monkeys.[2] Others have reported infection of monkeys with as little as 0.01 mg.[3] (1945) of feces. The amounts of virus developed in the central nervous system vary greatly from strain to strain. No data are available that permit direct comparison of titers of the same strain of virus in the feces and in the central nervous system. However, it has been our experience that the smallest amount of infected spinal cord that will cause infection on passage is frequently about 1 mg. or 0.1 mg. When one realizes that the amount of feces excreted by a young adult is in the neighborhood of 150 to 200 Gm. a day and that the spinal cord weighs only 34 to 38 Gm.[4] (1920), it becomes apparent that the total amount of virus excreted in feces may approximate the amounts present in the spinal cord.

It has been a general experience with poliomyelitis, as with other virus infections of the central nervous system, that maximal amounts of virus are present in the central nervous system at the time of severest clinical symptoms, or just before that stage is reached. As the acute form of illness subsides in monkeys with experimental infections the amount of virus present, or the ease with which transmission is accomplished, declines rapidly.[5] One week after an animal has become afebrile the chances of obtaining virus from a specimen of spinal cord are greatly reduced.

This general observation is in striking contrast to the repeated finding of virus in feces for weeks after an acute attack of poliomyelitis. According to the data in the study of Horstmann, Ward and Melnick[6] (1944) 27 per cent of persons excreted virus during the fifth and sixth weeks after the onset of symptoms of poliomyelitis. It seems difficult to account for the continued excretion of virus in feces on the basis of contamination from the nervous system.

If the prolonged excretion of virus in feces is to be explained as coming from the nervous system, one would expect to find evidence of extensive and progressive damage to the nerve cells supplying the intestinal tract. It has been shown that the presence of virus in large amount in any part of the central nervous system is regularly associated with extensive damage to the neurones in that area[7] (1930). One does not find clinical evidence of progressively severe dysfunction of the intestinal tract in persons convalescent from poliomyelitis and excreting the virus. This lack of significant neurologic damage to the intestinal tract must be considered as evidence against the idea that poliomyelitis virus in the feces is derived from the nerve cells supplying the intestine.

Additional evidence in favor of the idea that the virus of poliomyelitis may grow in cells other than those of the nervous system is provided by studies of Theiler's virus of encephalomyelitis of mice[8] (1941). It is well established that this virus may be excreted in the feces of mice over long periods of time. Symptoms of neurologic damage probably do not develop in over 1 of several thousand mice infected with the virus to the extent that they excrete it in their feces. This is true in spite of the fact that the virus when introduced into the central nervous system causes a severe and frequently fatal disease resembling poliomyelitis of man.

This virus is capable of spreading through the nervous system by way of neural pathways It seems unlikely that virus could invade the nerve cells of the intestinal tract and grow there for the long periods of time during which it can be found in feces without invading the central nervous system. Extraneural growth of this poliomyelitis-like virus is not proved but is a strong possibility.

It is recognized that none of the evidence presented proves conclusively that the poliomyelitis virus grows outside of nerve cells We have attempted, rather, to relate certain established facts that are extremely difficult to explain if it is assumed that the poliomyelitis virus grows exclusively in nerve cells The concept that poliomyelitis virus may grow in the human body outside of nerve cells is not new[9] (1942). However, the absence of definite proof of such extraneural growth of the virus has been construed by some to mean that the virus can grow only in nerve cells. In view of the data that have been reviewed this conclusion seems unjustifiable.

This question may be of more than academic importance. If extraneural growth of poliomyelitis virus is the basis for the excretion of virus in feces, such extraneural growth may be a necessary first step in infection with the virus. We visualize the possibility that small amounts of poliomyelitis virus, gaining entry into the alimentary canal, might be incapable of invading the nervous system until preliminary extraneural growth of virus has occurred.

Should this be the case, it is apparent that one possible method of preventing poliomyelitis would be to prevent the extraneural growth of the virus. It would seem reasonable, for example, to investigate the possibility of utilizing the interference phenomenon, or cell blockade, in this regard.

If the virus of poliomyelitis grows outside the nervous system, different strains of the virus should vary in their capacity to invade from the extraneural location into the central nervous system. One might find strains totally incapable of invading the central nervous system, although fully able to grow abundantly in the extraneural site A strain of this sort would be the type to use in any attempt to prevent poliomyelitis by employing the interference phenomenon

The fundamental studies of this phenomenon with plant viruses[10] (1940), with bacteriophage[11] (1942) and with mammalian infections[12] (1944) have already borne fruit in practical control of one mammalian virus disease, canine distemper[13] (1946). In view of the discouraging results that have come from the use of ordinary methods of immunologic control (vaccines and serum therapy), it would seem that serious consideration should be given to the newer and fundamentally different approach provided by the interference phenomenon The question whether extraneural growth of poliomyelitis virus is a necessary prerequisite to invasion of the nervous system then assumes critical importance

GROSS AUTOPSY OBSERVATIONS IN THE ANIMALS EXPOSED AT BIKINI

A Preliminary Report

JOHN L TULLIS
Commander (MC), U S N
and
SHIELDS WARREN
Captain, MC(S), U S N R

The unique opportunity to study the effect of massive ionizing radiations on experimental animals was provided by Operation Crossroads. The information obtained from observing the tissue response to stimuli provided by release of atomic energy is of medical, industrial and military interest. Radioactive and fissionable substances and their subsequent use presents many new hazards to health. Soon the methods for the prevention, diagnosis and treatment of ionizing radiation injuries should be familiar to all physicians

Because of the character and importance of the Bikini experiments, aid in the planning and the execution phases was obtained from scientists in civilian life, the Army, Navy and Public Health Services

It was considered that goats, pigs, white rats and guinea pigs would best meet the experimental needs These animals were chosen because of the wide range of their species' resistance to ionizing radiations Goats and pigs are approximately as sensitive to total body radiation as man, guinea pigs are more sensitive and rats are more resistant Ease of handling and feeding and the hardiness of the species were other factors influencing our choice of animals.

MATERIALS AND METHODS

In test "Able," the air explosion, 176 goats, 147 pigs, 3,130 rats (5 to a cage) and 57 guinea pigs were placed on twenty-two target ships. Twenty-nine goats, 48 pigs and 687 rats were retained on board the laboratory ship as controls The positions used for the placement of animals on the target ships covered the ship from masthead to below the water line and from bow to stern Locations on each ship offered varying amounts of shielding against ionizing radiation varying from no protection to the protection afforded by 6 or 8 inches (15 to 20 cm) of steel armor plate The object was to expose animals with just such amounts of shielding as members of the ship's crew might have.

For test "Baker," the shallow underwater explosion, 10 pigs were placed on each of two ships and 50 rats were placed on each of four ships in such a manner as to protect them from air, water and heat waves, yet afford only minimal shielding from ionizing radiation

Six boarding teams, which had placed the animals prior to the tests, reentered the target area as soon after the tests as the ships were pronounced safe for boarding The animals were returned to the laboratory ship, where they were individually examined for radioactivity and treated as indicated The living were placed in special pens and cage racks for observation. The dead were removed to the autopsy room for dissection and study.

Read in abbreviated form before the meeting of the American Association of Pathologists and Bacteriologists, Chicago, May 16 17, 1947
From the Naval Medical Research Institute, National Naval Medical Center, Bethesda, Md (Commander Tullis) and New England Deaconess Hospital, Boston (Captain Warren)

Three hundred rats, 100 from each of three target ships, were killed in groups of 30 a day beginning four days after test "Able." Also from time to time control goats, pigs and rats were killed for study. Tissue blocks from all organs of the animals autopsied were preserved in 10 per cent neutral solution of formaldehyde and in Bouin's solution. Microscopic sections of these tissues are being prepared at the Naval Medical Research Institute.

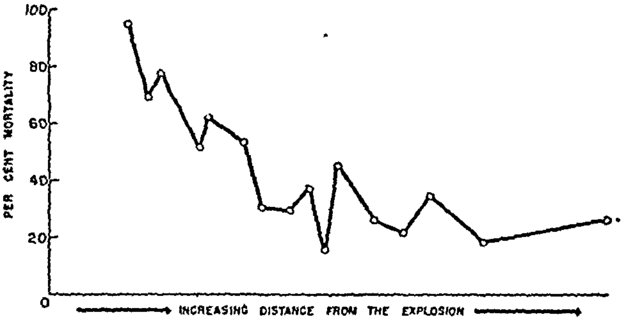

Fig. 1.—Mortality in rats—test "Able"

RESULTS

The atomic bomb contains all the explosive characteristics of trinitrotoluene magnified many times. In addition it produces ionizing radiations, which distinguish it from all other bombs.

The general mortality percentages for the animals exposed in the bomb tests (figs. 1 and 2) take into account deaths from all phases of the destructive power of the atomic bomb including air blast, thermal radiation, secondary fire and ionizing radiation. Loss by drowning is not included. It was not always possible to rule out certain factors which may have played a part in bringing about death, but in the Bikini tests ionizing radiations caused the greatest percentage of mortality. The animals placed for the shallow underwater explosion test were shielded from all effects of the blast except that of ionizing radiation. The mortality percentages in figure 2 represent deaths due to that cause only.

The animals which died from the effects of total body radiation died in the acute phase of the disease, and no deaths due to latent or chronic effects have been observed to date. Almost 100 per cent of the deaths occurred within one month after the tests. The greatest peak in the mortality occurred within two weeks. This was true in both tests and in all four species of animals.

The typical clinical picture of a goat or a pig, and to a lesser degree a rat, exposed to a lethal but not overwhelming dose of ionizing radiation showed an animal which at first looked and acted normally. The total white blood cell count decreased within a few hours, chiefly because of a fall in the number of lymphocytes, but within a few days the segmented cells also decreased. At the end of a week or ten days the red blood cell count showed a corresponding decrease. At that time or a little later the clotting and prothrombin times increased, clot retraction was altered and in some instances the bleeding time was increased.

After the first two or three days of apparent well-being of the animals there developed diarrhea, which in a week became bloody, tarry or both. They stayed on their feet but became hyperirritable and even belligerent at times. They took water but often refused food. As the anemia progressed, especially if the diarrhea persisted, weakness developed and the animals spent considerable time lying down. In the large animals, rapid panting respirations often were present from the first day or two after exposure to the bomb burst. They usually responded when approached, struggled to their feet and even walked, until suddenly they died. Death often was unexpected from clinical observations alone. When the diarrhea subsided and the respiratory distress abated the animals appeared to improve clinically, but when the tolerance dose of ionizing radiation was exceeded death was inevitable.

The gross pathologic lesions in goats and pigs which had died from the effects of overexposure to ionizing radiations were similar and were of three main types: hemorrhage, secondary infection and degenerative changes.

The earliest and most consistent lesions to appear were associated with hemorrhage, which became evident, particularly in the goats, pigs and guinea pigs, on or after the third day following exposure. The hemorrhagic lesions involved almost any or every tissue in the body. In the early stages of radiation injury dilatation and congestion of the small blood vessels of brain, heart, lungs, mesentery, bowel and subcutaneous tissue were the only observations. Later a few scattered petechiae were found in these tissues along with the hyperemia. In the animals which survived for five to ten days many petechiae expanded to ecchymoses or, occasionally, to small hematomas. The sites most frequently involved, singularly or in combination, were the heart and the gastrointestinal and genitourinary systems.

In the animals which had received large amounts of ionizing radiation, among both goats and pigs, petechial hemorrhages in the renal cortices and pelvic walls were common (fig. 3). Gross hemorrhage with blood clots in the kidney pelves was seen occasionally in the larger animals. The genitourinary lesions in guinea pigs were confined to petechiae in the renal substance, but this was rarely seen in the rats.

The diaphragm over the spleen was a favorite location for rather extensive extravasation of blood in goats and pigs. In guinea pigs widespread hemorrhage into the muscles of the back, the abdomen, the legs, the chest and the diaphragm was a fairly constant and decidedly striking manifestation of radiation. This intramuscular hemorrhage was the most characteristic lesion in the guinea pigs. It was practically never seen in the rats but occasionally was seen in the goats and pigs.

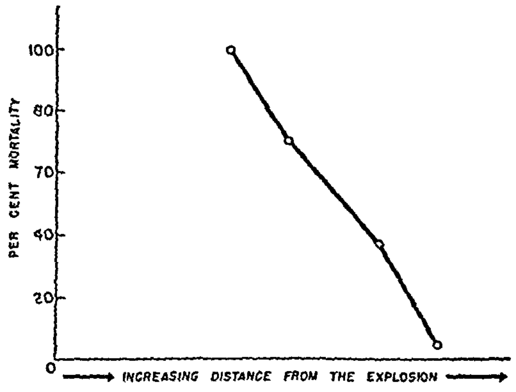

Fig. 2.—Mortality in rats—test "Baker"

In all species the lymph nodes, particularly of the cervical, preaortic, mesenteric and inguinal regions were characteristically hemorrhagic. Usually the nodes were enlarged, but their chief distinguishing feature was their dark red color, interspersed on the cut surface with patches of moist gray lymphoid tissue. They were uniform in appearance in all regions of the body. The brain and meninges sometimes contained petechiae, and the skin, particularly in the "Baker" pigs, frequently showed purpuric lesions.

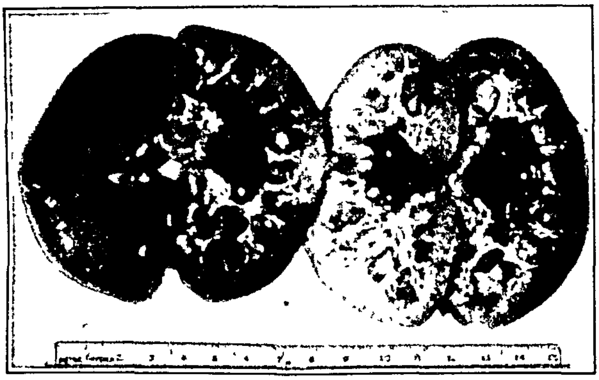

Fig. 3.—Hemorrhage into the cortex, medulla and pelvis of the kidneys of a pig exposed in test "Baker."

In about 80 per cent of the deaths, the lungs were mottled dark red and pink; the cut surface was wet and sometimes dripped blood-stained fluid, and the bronchi were filled with abundant pink or white froth. The dark red patches were irregular but usually sharply outlined and firm, resembling areas of hemorrhagic lobular pneumonia. Lobar consolidation was seldom seen.

The gastrointestinal tract presented a third type of lesion manifested chiefly in the large intestine. In the first three or four days after exposure, acute ulceration of the large intestine sometimes occurred in the absence of gross hemorrhagic lesions. The ulcers were small, irregular and often elongated in the longitudinal axis of the bowel (fig. 4). They were always superficial and never extended deeper than the submucosa. Covering the surface were tenacious, feces-stained, fibrin membranes, which were removed with difficulty, leaving a raw and moist surface beneath. Later similar ulcerations were surrounded by swollen hemorrhagic mucosa. Although the layers of the bowel external to the mucosa were usually edematous and hemorrhagic and were often spotted with petechiae, there was no evidence of perforation or peritonitis. The stomach sometimes contained similar ulcerations. Usually the small intestine showed petechial hemorrhages in the muscular layer, but the mucosa appeared normal. However, the pigs exposed in the "Baker" test sometimes showed ulcerations in the mucosa of the entire small intestine as well as in the stomach and large bowel. The ulcerations of the small intestines were accompanied by less edema and usually were not covered with a fibrinous membrane. A striking feature in all these ulcerations was the absence of gross purulent reaction.

In the tonsils shallow, fibrin-covered, irregular ulcerations similar to those seen in the colon were fairly common. The ulcerations appeared to spread from areas of petechial hemorrhage.

The liver, spleen and adrenals were essentially normal. The bone marrow sometimes was pale and sometimes hyperemic without obvious relation to the general disease state of the animal.

SUMMARY AND CONCLUSIONS

Clinical observations are readily correlated with the pathologic observations. Severe radiation sickness is associated with depression of the hematopoietic centers and increased capillary permeability. Capillary dilatation and probably damage to intercellular cement substance combine to bring about extravasation of blood which is recognized clinically as petechiae, ecchymoses and, sometimes, small hematomas. Degenerative changes may result in ulceration of the gastrointestinal tract which, when it occurs, causes diarrhea and is responsible for considerable hematic loss. Loss of blood into the tissues and externally is largely responsible for the anemia which appears in the second week. Action of the ionizing radiations on the circulating white blood cells is possible and may account in part for the early leukopenia, but the chief factor in the development of continued leukopenia or agranulocytosis is the damage to the bone marrow.

Anemia and leukopenia are responsible for the weakness, irritability and lowered resistance to infection. Degeneration of tissue leads to absorption of toxic breakdown products from the injured cells.

Death in the first month after exposure to lethal amounts of ionizing radiation is apparently the result of three factors working singly or in combination: anemia, secondary infection and/or toxemia associated with the degeneration of tissue.

In the Bikini animals nearly 100 per cent of the mortality due to ionizing radiation injury occurred within the first month, with the greatest peak at two weeks after exposure. The tests were designed to study all phases of the destructive power of the atomic bomb, but ionizing radiations accounted for the great majority of deaths.

Severe burns were few in number. The exposed animals were well protected by their fur. In those cases in which anti-flash-burn cream was applied to the depilated skin of the animals full protection was afforded.

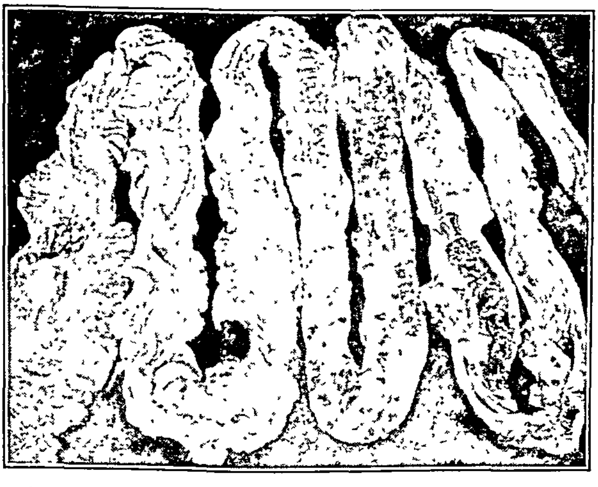

Fig. 4.—Hemorrhage and ulceration in the mucosa of the large intestine of a pig exposed in test "Baker."

Air blast injuries will be the subject of a special report, but it may be stated here that they were not common causes of death.

From the data presented several conclusions seem justified.

1. Ionizing radiations of the atomic bomb are lethal for goats, pigs, guinea pigs and rats exposed to them under varying conditions.
2. The gross pathologic observations are fairly characteristic and similar in the four species studied.
3. The sensitivity to ionizing radiations varies somewhat among the four species, the guinea pigs being by far the most sensitive, the pigs being slightly more sensitive than the goats and the rats comparatively resistant.
4. The flimsiest of shielding seems to afford ample protection from thermal radiation, but heavy armor does not always protect from the ionizing radiations.
5. An underwater atomic bomb explosion is more lethal than an air explosion, since the spray which showers down on the ships in the vicinity carries with it fission products which contaminate their surfaces, cannot be removed easily and remain dangerously radioactive for long periods of time.

TREATMENT OF INFECTIONS OF THE NECK

CARL H. McCASKEY, M.D.
Indianapolis

A discussion of the treatment of infections of the neck should entail the following: first, the fascial planes of the neck; second, the area from which the infection arises; third, the types of organisms which are present, and fourth, the medical and surgical treatment of the infection.

The fascial planes of the neck

The fascia is a sheet or band of tissue which invests and connects muscles and other functional structures, such as neurovascular bundles, with the viscera. The fascia consists of a waxy matrix of fibrous and fatty fibroareolar tissue cells in various proportions as to cellular components, depending on the position and functional requirements.

Genetically, the fasciae are composed of the same type of connective tissue cells which are utilized in the formation of the supportive framework and the covering of muscles, blood vessels, nerves and viscera. The fasciae are structurally identical with the periosteum and muscle tendons and with the supportive framework of the serous membranes. As a matter of fact the fasciae cover and blend with the external coat of all the important organs of the body; namely, blood vessels, nerves, bones, muscles and most of the viscera.

The surgeons are familiar with the fascial interspaces as lines of cleavage. The fascial interspaces also serve as paths of least resistance for the spread of infection, neoplasms or foreign bodies. Despite their well known clinical importance the fasciae are less well comprehended than any other structures studied in gross anatomy. The textbook descriptions of the fasciae are, as a rule, based on observations in the cadaver and are, therefore, complicated and variable.

The fibroareolar tissue is relatively soft, pliable and elastic, whereas in the cadaver the fasciae are pultaceous and of suetlike consistency. It must be remembered that the technic of surgery requires exposure with minimum trauma and display of anatomic structure.

One might criticize the conception of the fascia which is ordinarily presented to the student as purely academic and based on dead anatomy.

The following are some of the difficulties encountered in understanding the fascia:

1. Discrepancies in description by different authors (American, English, French and German).
2. Variations in terminology.
3. Failure to appreciate the important part played by the fascia in the mechanical functions of the body.
4. Failure to appreciate fundamental morphologic principles.
   a. The primary tissues are primarily supportive.
   b. All connective tissues are derived from the mesenchyma, and all are modifications of the fibroblast or the fibril connective tissue cells.
5. The so-called interfascial spaces are filled or made up of filmy fatty fibroareolar tissue which infiltrates in the so-called tubular sheathes and serves the important function of support, of insulation and of separating the various functional units. The spaces are of various sizes and contain connective tissue elements of various degrees of density depending on functional requirements.

At the risk of oversimplifying the problem of the connective tissues of the body it should be emphasized that, after all, the connective tissues have only two functions; first, they tie structures together and second, they keep structures apart.

It is true that pus tends to gravitate or progress along the paths of least resistance, which is through the substances of the soft supportive intermembranous spaces.

The area from which the infection originates

The area from which the infection originates is of prime importance, and careful inquiry into the history of the portal of entrance is important for the reason that evidence of inflammatory reaction may have disappeared by the time there is evidence of the infection of the neck.

In case of infection in the neck from dental extraction the secondary sequelae of infection in the neck may occur ten days to two weeks after extraction of the tooth. On the other hand, the infection in the neck may follow the extraction immediately.

The tonsils, cervical vertebrae, nasal sinuses, temporal bones, salivary glands, esophagus and respiratory tract and injuries about the hypopharynx, larynx, trachea and esophagus are often the sources of infection in the neck. Fracture of the sinuses, especially the maxillary, or fracture of the mandible is frequently followed by cervical infection. The infection in the neck may be relayed from any of these areas.

If the source of the infection can be determined it will give a clue as to the course the infection may follow and the probable point of localization.

A peritonsillar abscess, following tonsillitis, is one of the commonest infections of the neck. This may have as a complication a subtonsillar abscess, a parapharyngeal abscess or a pharyngomaxillary abscess.

The next most commonly observed cervical infection is that of the pharyngomaxillary space following the removal of tonsils under local anesthesia. This may be opened and drained intraorally or externally by using the Mosher technic. An infection in this region may extend downward by way of the pharyngomaxillary space and involve the pretracheal fascia, thereby producing an edema of the larynx which in turn may result

Read before the Section on Laryngology, Otology and Rhinology at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 3, 1946.

in an extremely grave situation. It may burrow its way into the carotid sheath and break through, causing an internal jugular thrombosis.

Mastoid infection may reach the neck by at least four different routes. First, a Bezold's abscess may follow the posterior belly of the digastric muscle by breaking through the digastric groove and reaching the carotid sheath, thereby causing an internal jugular thrombosis. Second, infection in the petrous pyramid of the temporal bone may break through at the inferior surface following under the periosteum, reaching the prevertebral space and laterally the pharyngomaxillary space, then into the carotid sheath and involve the internal jugular. Third, an infection may break through the zygomatic cells and involve the pharyngomaxillary fossae. Fourth, an infection may break through to the neck by way of a lateral sinus, when thrombosed, which may extend directly into the carotid sheath.

The types of organisms which are present

If a smear or culture can be obtained early from the site in which the original infection is located, there is a much better chance of providing early medical therapy. If neither of these can be obtained a knowledge of the organisms which are habitués of this area must be had, or the patient must relate just what occurred which may have been responsible for the start of the cervical infection. The most commonly found types of organisms in infections of the neck are the streptococcus, staphylococcus and, occasionally, the pneumococcus. Other types are Borrelia vincenti, Clostridium perfringens and Mycobacterium tuberculosis.

In the treatment of infections of the neck before the formation of pus, chemotherapy is turned to; that is, sulfonamide compounds, penicillin or streptomycin. The relative value of each of these drugs is shown in table 1.

The medical and surgical treatment of the infection

The local application of sulfonamide drugs in cervical wounds of the lacerative type after débridement was reported to be of great value during World War II.

When there is evidence of a beginning purulent infection of the neck and there is a primary focus of infection, this must be drained in order to give chemotherapeutic agents a better chance to relieve the cervical infection.

Table 1.—*The Relative Value of Sulfonamide Drugs, Penicillin and Streptomycin in Infections of the Neck*

	Sulfonamide Drugs	Penicillin	Streptomycin
Streptococcus	++++	+++++	0
	+++	++++	0
	++	+++	+ – ?
	0	++++	+ –
	+ ?	++	0
	+	0	++ ?

If, after draining or controlling the local site of the infection, with both medicaments and surgical drainage, the infection in the neck gives evidence of going on to localization with the formation of pus, there is but one thing to do, and that is to institute surgical drainage.

The areas in which pus is most likely to form are shown in table 2.

The early recognition and proper management of these abscesses calls for a thorough knowledge of the anatomy of the regions concerned as well as surgical judgment and skill. The seriousness of these conditions lies in their tendency to spread along fascial planes and invade the thorax with a resulting mediastinitis.

Relationships are often lost due to the swelling from infection, and tissues are matted together and distended. The surgeon under these conditions must allow for great displacement and often confusing changes in tissue appearances caused by the presence of the abscess. Thus pure anatomic relationships become disturbed.

Table 2.—*Spaces of the Neck in Which Potential Infection May Occur*

Submental	Submaxillary Space	Pharyngomaxillary Space
Teeth Submaxillary space	Teeth Suppurating lymph glands Abscess of submaxillary gland	Retropharyngeal abscess Peritonsillar abscess Post-tonsillectomy abscess Suppurating jugular lymph nodes Teeth

Prevertebral Space	Submental and Submaxillary Space
Infected lymph gland Necrosing tuberculous vertebrae	Infection from wounds Teeth causing Ludwig's angina

One type of cervical infection which especially warrants mentioning is Ludwig's angina. This is a phlegmonous induration of the cellular tissues of the neck which produces a wooden-like hardness on which no impression can be made by palpation.

Anatomically the site of this induration is in the cellular tissues in the floor of the mouth and submaxillary region, usually below the mylohyoid muscle; it frequently extends into the sublingual region and is limited laterally by the horizontal portion of the mandible and inferiorly by the hyoid bone. The treatment of this lesion is radical and is as follows: Under local anesthesia a wide surgical horizontal incision is made, and the wound is left open with free drainage.

CONCLUSIONS

In the treatment of infections of the neck the following considerations are important:

1. It is necessary to know the fascial planes of the neck.
2. The site of the original infection should be discovered.
3. A knowledge of the bacteriologic cause of the infection is essential.
4. The type of medical treatment which is to be employed should be more or less specific for the organism present.
5. The selection of the proper time to perform surgical drainage is important.

ABSTRACT OF DISCUSSION

Dr. J. M. Brown, Los Angeles: I agree with the principles laid down in this paper, especially the anatomic part. I should like to mention a few etiologic factors that have a bearing on the treatment. One is the invasion of the connective tissue in the various fascial planes that Dr. McCaskey has mentioned, such as lesions following the extraction of teeth and abscesses coming down from the petrous portion of the temporal bone. When this condition is present in the tissues of the neck, the patient is decidedly sick and needs immediate attention. The second factor is that frequently a lymph node is infected for an indefinite time and then breaks down. This is a slower process, but one must be on guard and the minute the node has broken down, immediate drainage is to be instituted, thus preventing the cellulitis. The third is that of phlebitis and thrombophlebitis, which have few local symptoms. A serious phlebitis may be present with few local manifestations. This also requires immediate attention surgically because of serious complications by emboli. When a patient is admitted to the hospital with a cervical infection, it is first determined if there is any laryngeal obstruction. If it is pronounced, a tracheotomy is performed at once and a large dose of penicillin is given. If the dyspnea is of moderate severity and it is believed that pus is present in the infected area, the pus is evacuated before the performance of a tracheotomy, and in most instances the latter is found necessary. The chief anchor in these patients is penicillin. Before penicillin could be obtained, sulfonamide drugs were used and found to be of little value. Penicillin is of distinct value in stopping the cellulitis, but it will not absorb pus. As soon as one is satisfied that pus is present, the infection should be drained; local anesthetic is preferable. A general anesthetic is given only when an intratracheal tube can be used, which is not often. I have found that early incision and drainage of the affected area, plus the administration of penicillin, is the best treatment. I should like to mention one other type of neck disturbance having all the appearances of a Ludwig's angina. Three patients were admitted to the Los Angeles County Hospital with difficulty in respiration and swelling in the neck and mouth, similar in appearance to a Ludwig's. There was no tenderness or boardlike feeling and no elevation of temperature. On physical and laboratory examinations the patients were found to have nephritis, and the cervical and oral swelling was a part of the renal disease.

Dr. Rea E. Ashley; San Francisco: General immunity and local tissue immunity play an important part in preventing the extension of these infections. Certain physiologic and anatomic barriers also tend to limit the spread of these infections to the adjacent and deeper tissues of the neck. The lymph system is highly developed in the neck, and the lymph nodes constitute a series of traps for invading bacteria. Various layers of cervical fascia act as mechanical barriers to extension of the infection. Prophylaxis is most important. Early use of the sulfonamide compounds at the original site of the infection and early administration of large doses of penicillin at the first sign of complication will frequently prevent or stop extension of the infection. Once the infection has broken through, however, and symptoms of deep suppuration develop, a critical stage exists which will tax any surgeon's ingenuity and demand his best surgical judgment. No rule of thumb can be set up as to the best time to operate. That is a matter of surgical judgment. Once the decision has been made, however, and the point of incision decided on, the surgical intervention should be radical and deep. Dr. McCaskey has given a clear and concise definition of fascial interspaces and has rationalized the method by which infections spread into the deep tissues of the neck. He has also outlined the general treatment so well that little can be added in the way of discussion. The history will frequently give a clue to the path which the infection is most likely to take and the probable point of localization. The types of organisms at the original site of the infection may give a clue to the drug most likely to be effective in medical treatment. Most important is the intimate knowledge of the fascial planes of the neck. Deep infections of the neck are far less common in medical practice today than they were ten to fifteen years ago. This, I believe, is due to more universal prophylaxis, the development of the sulfonamide drugs and the use of penicillin. The number has so appreciably decreased that I believe it is not fantastic to prophesy that in a short time deep infections of the neck will be rare.

Dr. Thomas E. Carmody, Denver: Many years ago Barnhill, Beck and I recommended that the field of otolaryngology be enlarged. I note that some of the speakers in the last year or two are recommending that. Dr. McCaskey has called attention to the mouth, which is something that was not mentioned a few years back. Many of the cases of Ludwig's angina (an-ji'nah)—I say that instead of McCaskey's angina (an'jin-ah)—originate in the mouth from an infection not only of dental abscesses but peridental abscesses and abscesses underneath the periosteum. Many of these abscesses are not found immediately, as Dr. McCaskey has said, but it requires eight or ten days before they will show up in the mouth even with roentgen examination, so that one needs to consider the delay in locating those besides the fact that the infection of the neck does not show up early. Osteomyelitis occurs frequently in these cases, and then it extends down into the floor of the mouth, either below the mylohyoid or above the mylohyoid, resulting in infection of the salivary glands, the peritonsillar spaces or the tonsillar spaces. There are also infections which travel downward. These not only affect the trachea but affect the post-tracheal fascia, and will extend into the mediastinum. Unless they are treated early, they will cause a great deal of trouble. Before the chemical drugs of today were available, roentgen radiation was frequently used to localize some of these infections, and it helped in many of them. Dr. McCaskey spoke of tracheotomy. Unless it is done early, it is of very little use. The abscesses should be opened and opened low enough. I have made the mistake of opening them high; the infection followed the muscle planes very low, and I had to open the abscesses lower down later on. Some patients were lost; some I was able to save.

Dr. Burt R. Shurly, Detroit: It gives me a great deal of pleasure to find that the general surgical problem is being treated more seriously by special workers in this field than it was in the past. This paper is timely and exceedingly fine. With this new era and with the current readjustment, individual and collective, this specialty is undergoing some of that change. The demand for an extension of our work to the borderline surgical fields is timely and necessary, and the members of the American Board are particularly interested in trying to help younger men to obtain a finer general surgical training. Particularly in recent time, the Board of General Surgery is cooperating in that questions on general surgical practice will be brought before those who come to examination. The interns and the residents, it is hoped will take perhaps an extra year of general surgical training. This subject of infections in the neck is one—it has been here always, and I feel that one should be qualified and competent to take on whatever may be necessary, surgically, medically or otherwise. In my earlier days one met with much bovine tuberculosis, in which the glands of the neck were involved, and surgical intervention was performed to remove those glands in a great many cases. Now, with the wonderful prevention of bovine tuberculosis and the marvelous health work, those glands infected by bovine tuberculosis have certainly diminished in a marvelous way. I feel keenly the tremendous value of sulfonamide drugs and penicillin. In the days of early diphtheria antitoxin, physicians were a bit tardy in giving sufficient dosage, and I consider that to be true now of a great many in the use of the sulfonamide drugs and penicillin. I have had a considerable number of patients with neck infections, tonsillitis, peritonsillitis and mastoids that have almost died. Over in Detroit and, I think, throughout the country at large, medical practice has been wonderfully influenced by what I think is the finest of the compounds, sulfadiazine and soda in large, sufficient and carefully watched dosage, and large doses of penicillin given intramuscularly promptly, early and plenty of them. This new era has come to the specialty with a tremendous value, which should be taken advantage of in the earliest stages of infection and followed through, never neglecting surgical intervention when the formation of pus makes that imperative.

Dr. Irving Wilson Voorhees, New York: My experience with these cases has been more limited than that of Dr. Shurly or Dr. Carmody. Over the past forty years I have seen 4 cases, all of them in private practice. All these cases followed dental extraction, except one, which was a deep infection following an unrecognized latent peritonsillar abscess on the right side. That patient had an early tracheotomy. Surgical intervention was performed following the tracheotomy, and the patient recovered in about three weeks. The important case was that of a gas bacillus infection in the left side of the neck following extraction of the lower teeth. This began about three days after the extraction, with a large hard swelling in the neck. Nothing was done until I saw the patient about five days after extraction. The dentist had sacrificed the tooth area, probably spreading the infection somewhat. The case was then turned over to a general surgeon, who made a small incision.

The whole area should be widely exposed, even if no pus is found, because the tension must be taken off the tissues and off the trachea so that tracheotomy may not become necessary. The timidity and the delay of some surgeons in not doing early tracheotomy needs to be emphasized. If one is going to do it at all, do it early. In this case all the tissues of the left side of the neck broke down. The muscles became a tarry, foul, stinking mass. They could be picked out by forceps. There was an opening from the mouth into the neck. The carotid was exposed and was seen pulsating. The gas bacillus was found in pure culture. The neck was irrigated every two hours with strong peroxide of hydrogen. I did not know then about penicillin or streptomycin or about introducing oxygen gas into the tissues. But I feel that in this particular case the oxygen "lavage" saved the man's life.

Dr. B. M. Kully, Los Angeles: As I listened to this excellent paper and the discussion, there was one point that came to my mind which I think should be emphasized. All use large doses of penicillin, but I think it should be remembered that penicillin may kill off the infection and not cause an absorption of the pus. There may be an abscess after the infection is gone. I should like to cite a case. A man came to me—he was a major in the Army—and gave a history of having been treated for a throat infection five months previously. I was able to contact his medical officer and found that he was given large doses of penicillin for a retropharyngeal cellulitis. He told me that his throat had never been right since and that he had some difficulty in swallowing. On examination he had a bulging of the posterior wall of his hypopharynx, low down just above his arytenoids. I aspirated it, got pure pus and a negative culture. It was incised and the man's symptoms were completely relieved. This was not a tuberculous abscess, because there was no involvement of the bone, and the man made an uneventful recovery. To me the case points to the fact that pus, even if all signs of infection have subsided, must be evacuated.

Dr. Carl H. McCaskey, Indianapolis: The first argument that I have to make is with Dr. Carmody. He and I have had friendly discussions on the pronunciation of angina (an'jin-ah) or angina (an-ji'nah). We in Indiana like angina (an'jin-ah) and we call it angina (an'jin-ah). The usage of a word determines the pronunciation, isn't that right, Dr. Carmody? (Dr. Carmody nodded his head.) All right, we have that settled. Dr. Brown's case of nephritis was interesting and shows that one should not jump to a conclusion in making a diagnosis. After he had carefully examined the patient and found his condition to be due to a nephritis, it set up an entirely different picture as to treatment. Dr. Ashley's discussion relative to the general handling of these cases was quite pertinent. With regard to chemotherapy, it is generally known that organisms become fast to chemotherapeutic agents. That is cited in the last case. Perhaps this person had become fast to the chemotherapy that had been administered to him. This also holds good for a period of time after the administration of these agents. For instance, every one, including me, grabs at the chemotherapeutic agents for almost every type of infection that comes along, without any rhyme or reason. If one is treating infection of the neck or infection anywhere it is well to know the type of infection with which one is dealing and the type of chemotherapeutic agent which applies particularly to that organism. That is the reason I mentioned that one should, if unable to find the type of organism from smear or culture, at least be well acquainted with the type of organisms which inhabit the area. Therefore, one has some clue to the type of treatment to be followed. The chemotherapeutic agents will not absorb pus. One must drain it to get results, and that goes for the original site of infection. For instance, in an acute mastoid infection, if there is pus in the neck and in the mastoid, the mastoid abscess must be drained before relief will be obtained from drainage of the pus in the neck. I brought up this subject only for this particular reason: I hoped that a greater number of surgeons would become interested in some of these conditions of the neck. No one should attempt to do surgery of the neck who is not well prepared for it. He must know his anatomy, his pathology and his bacteriology.

THE PROBLEM OF GASTRIC CANCER

OWEN H. WANGENSTEEN, M.D.
Minneapolis

A diagnosis of cancer of the stomach strikes fear into the hearts of patients. And well it might, when it is realized how relatively small the ultimate salvage of life is in patients whose disease is so diagnosed. One of the most favorable reports, that of Walters, Gray and Priestley[1] (1942) has suggested that only 6 per cent of their patients whose disease is diagnosed as gastric cancer are alive five years later. Weese[2] (1940) stated that of 883 patients admitted to the Tübingen Surgical Clinic between 1921 and 1932, only 8 per cent were alive five years later. Livingston and Pack[3] (1939) stated that definitive cures of unselected patients with gastric cancer is probably in the range of 2 per cent. In other words, it appears that 92 to 98 per cent of patients who have gastric cancer will die of the disease within five years. However, of patients who survive resection for gastric cancer for a period of five to seven years, Berkson[4] (1942) has expressed the belief that the subsequent life expectancy is about the same as for normal persons. The irony of the matter is that approximately only 25 per cent of patients who have gastric cancer are suitable candidates for a curative type of operation. In the Mayo Clinic series of those who survived resection (traced patients) 28.9 per cent survived five years and 20.4 per cent ten years. Of the resected cases in the Tübingen series, 19 per cent were alive five years later. Gastric cancer is curable, but the problem is to recognize the presence of the disease in time, so that the patient will not be denied the real hope that timely and well performed surgical intervention holds out to sufferers from gastric cancer.

Moreover, cancer of the stomach is the most frequent of all malignant growths. In regard to its incidence, Livingston and Pack[3] (1939) have written the following: "There are more deaths from cancer of the stomach than from all malignant tumors of lip, tongue, cheek, tonsil, pharynx, larynx, salivary glands, thyroid, male and female, breast, ovary, uterine cervix and corpus uteri *combined*." Cramer[5] (1937) has stated that, from country to country (European), the incidence of cancer in a certain organ may vary considerably; yet the overall mortality of cancer for populations of various countries is approximately the same. The death rate for cancer of the stomach is high in almost all countries, and deaths from gastric cancer comprise from 25 to 40 per cent of all deaths from cancer.

Deaths from cancer in this country rank only next to cardiac disease as the most frequent cause of death. And of the 150,000 annual deaths from cancer in the United States, approximately 40,000 persons die of gastric cancer. Moreover, as the proportion of aging people in the population increases, it is obvious that

the total number of deaths from cancer as well as gastric cancer will increase. Truly, cancer and especially gastric cancer, the most frequent of all cancers, is a problem of public health of first importance.

ETIOLOGY

Experimental.—Fibiger's[6] (1913) conclusion that the eating by rats of cockroaches infested with Gongylonema neoplasticum was the cause of spontaneously occurring gastric cancers observed in those rats has been set aside by the demonstration that a similar papillomatosis of the preventriculus can be brought about in mice and rats by a vitamin A deficient diet.[7] Lorenz and Stewart[8] (1941) have observed the occurrence of an adenocarcinoma in the glandular portion of the stomachs of mice after the injection of 20-methylcholanthrene into the gastric wall. They have also obtained similar malignant tumors of both the stomach and intestine by the oral administration of 20-methylcholanthrene in light liquid petrolatum.[9] Strong,[10] (1945) employing hybridized mice, succeeded in perpetuating the carcinogenic influence of methylcholanthrene in subsequent generations of mice without continuing the administration of the carcinogen. Roffo[11] (1939) stated that he produced adenocarcinoma as well as sarcomas in rats fed fats or cholesterol heated to 300 C., a claim which is still awaiting confirmation. Peacock and Kirby[7b] (1944) have shown that, unlike benign gastropapillomatosis associated with dietary deficiency, papillomas induced with carcinogenic hydrocarbons (20-methylcholanthrene) are not prevented and fail to disappear with the addition of large amounts of vitamin A to the diet. An excellent review of the experimental aspects of gastric cancer was written by Peacock[12] of Glasgow, Scotland, in 1943. Excellent reviews have been published by Klein and Palmer[13] (1941) and Ivy[14] (1945).

Clinical.—On the clinical side, there is a wide diversity of opinion concerning the origins of gastric cancer. Most authorities agree that gastric cancer probably does not originate *de novo* from a normal gastric mucous membrane. There is no unanimity of opinion, however, concerning the importance of items which it is believed may give special encouragement to the development of gastric cancer; among these are to be enumerated: (1) the benign polyp, (2) atrophic gastritis and (3) gastric ulcer.

Ulcer.—Much debate has hedged about the problem of the extent to which a benign ulcer may favor the development of gastric cancer. Much of that discussion has generated more heat than light. However, there can be no doubt concerning the finality of the proof that cancer occasionally develops in a gastric ulcer. Every gastric surgeon of experience has seen large gastric ulcers which are found to be benign after excision. After a few years the patient may return with unmistakable evidence of cancer in the residual gastric fragment. A more detailed examination of the ulcer by the pathologist usually succeeds in finding the area which was carcinomatous in the initial specimen. Two such cases have been observed in this clinic within the past few years. These ulcer-cancers in which the malignant growth occupies only a small portion of an ulcer of long standing have been well described by pathologists. In addition, several patients have been seen in whom a gastrojejunostomy had been made previously elsewhere for benign gastric ulcer. With the lapse of years, gastric cancer may follow. This occurrence has been noted in patients in this clinic as long as eight and in 1 instance twenty-five years after the performance of the gastrojejunostomy.

No one doubts the thesis that an unhealed burn, a chronic sinus or an ulcer on the surface of the body may give rise to a cancer. There seems to be little reason to doubt that this same transition may occur in a gastric ulcer. Moreover, Magnus[15] (1937) has reported that a moderate to a severe degree of atrophic gastritis has been observed by him in every gastric ulcer specimen examined.

An even more cogent reason for looking on the gastric ulcer with suspicion is that the hazard of confusing benign and malignant ulcers is real. In other words, no reliable criteria are available to distinguish sharply and consistently by diagnostic means between benign and malignant gastric ulcer. For the stomach as a whole, it has been said that approximately 10 per cent of ulcers which are believed to be benign by conventional diagnostic measures are found to be cancerous when the ulcer is removed. Moreover in the immediate prepyloric area, the Boston group of observers have stated their belief that cancerous ulcers outnumber benign ulcers three to one.[16] Finsterer[17] (1938) has expressed the belief that if patients with ulcerocancer underwent operative intervention six months to a year earlier the cures would be about 90 per cent.

Since gastric resection for ulcer can be performed by the experienced surgeon at risks well below 5 per cent, there seems little justification for the physician to assume so conservative an attitude toward the chronic gastric ulcer that the patient's future may be compromised thereby. This is one of many factors which contribute to delay in bringing the patient with gastric cancer for early operation.

Atrophic Gastritis.—Konjetzny[18] has been the keenest proponent of atrophic gastritis as a frequent precursor of gastric cancer. Schindler[19] has also favored this view. This idea gets its strongest support from the frequency with which pernicious anemia is complicated by gastric cancer. That atrophic gastritis is a regular accompaniment of pernicious anemia has long been known. Magnus and Ungley[20] (1938) pointed out that the atrophy is not patchy in pernicious anemia as in most idiopathic achlorhydrias but is diffuse and moreover involves all the layers of the gastric wall, especially the corpus and fundus, resulting in a parchment-like thinness of the stomach. Kaplan and Rigler[21] (1945) have stated that the incidence of gastric cancer in patients dying of pernicious anemia is 12.3 per cent, or three times the expected autopsy incidence of gastric cancer in patients belonging to the same age group. Rhoads[22] (1941) previously had summarized the clinical and pathologic evidence relative to the relation of pernicious anemia to gastric cancer. His observations are in general accord with those of Kaplan and Rigler. Moreover, gastric polyps are of frequent occurrence in the atrophic gastric mucous membrane of patients with pernicious anemia. Madelaine Brown[23] (1934) pointed out this unexpected association in an autopsy survey of patients who had died of pernicious anemia, an observation which Kaplan and Rigler later confirmed.

Rodgers and Jones[24] (1938) noted the presence of superficial hemorrhagic erosions and ulcers on gastroscopic examination of patients with atrophic gastritis and idiopathic achlorhydria. This is an important finding, and one which justifies continued observation to determine the fate of such erosions.

Polyps.—Most authors who have studied precursors of gastric cancer have incriminated the polyp, including Borrmann[25] (1926), Konjetzny[18a] (1938), Schindler[19] (1941) and Westhues[26] (1942). Tracy Mallory[27] (1940) has described the presence of noninvasive carcinoma in situ in gastric polyps and has stated that "their pronounced tendency toward malignant degeneration" is generally admitted. Kaplan and Rigler[21] wrote concerning the gastric polyp found in patients having pernicious anemia that: "the demonstration of gastric polyps in association with pernicious anemia has almost the same significance as the demonstration of carcinoma *per se.*" Westhues[26] (1942) expressed the belief that most gastric polyps are essentially tumors and are not the result of inflammatory gastritis, as is suggested in the work of Konjetzny. Spriggs and Marxer[28] (1943), however, dissented from this view and have followed a number of patients with gastric polyps over a period of years without observing evidences of cancer.

In this clinic a study has been made of patients past 50 years of age who are achlorhydric to histamine, and a fairly large number of such polyps have been discovered. At present 15 are under observation. At one time the majority opinion in this matter was followed and the gastric polyp was regarded as a likely precursor of gastric cancer, which, with the passage of sufficient time, it well may be. After the performance of gastric resection for a fairly large number of such patients, there has finally been a reversion to the policy of following them three or four times a year by gastroscopic and roentgen examinations. At present there are 2 such patients under observation, who have both pernicious anemia and gastric polyps.

The description of Borrmann[25] (1926), Mallory[27] (1940) and others of heteropia of the gastric mucous membrane in such polyps together with histologic evidence of noninvasive cancer suggests obviously the need for caution in pursuing a conservative policy. Moreover, in 1 instance a patient who underwent gastric resection for benign polyp in 1941 returned with gastric bleeding three years later but at that time refused to permit reoperation. When pain again recurred the patient acceded to operative intervention (1945), but an irremovable cancer, which had spread beyond the confines of the residual gastric pouch, was found.

Unfortunately, biopsy cannot readily be performed through a gastroscope. It may well be that occasional removal of such allegedly benign gastric polyps through a small abdominal incision will be warranted in the light of the great practical importance of the considerations involved.

EXTRINSIC FACTORS

There is a sharp difference of opinion among persons interested and experienced in the problem of gastric cancer in regard to the rôle of extrinsic factors in the origin of gastric cancer in man. There are those who believe that the so-called constitutional susceptibility is important. Others would indict in such an analysis exogenous factors, particularly diet. Nettleship[29] (1943) has discussed this problem in an interesting and informative manner and has listed such factors as diet, age, heredity, heat, alcohol, bacteria, viruses, allergy and infections.

The influence of temperature of ingested liquids and food and the irritant quality of liqueurs, alcohol, spices and rough foods on the esophageal or gastric mucous membranes must perforce be considered. When, however, one reaches the lower alimentary tract, especially the rectum and colon, all such influences have been dissipated. Then, apart from so-called constitutional predisposition, the important question arises of carcinogens in the intestinal content itself.

Age is, of course, an important determinant in all forms of cancer. Herring[30] (1936) has pointed out that states with the largest percentage of their population above 45 years of age have the largest mortality due to cancer. New Hampshire, with 30.3 per cent of its people above 45, has an annual cancer mortality rate of 155.4 per 100,000, the highest in the United States.

Dr. David State of this clinic has undertaken the task of interrogating the relatives of patients with gastric cancer to determine the frequency of cancer in their families. In the families of 200 patients with gastric cancer, a history of cancer was obtained in 31.6 per cent; in half of these instances (15.6 per cent) a history of gastric cancer was elicited. Dr. State interrogated the relatives of 200 patients with gallbladder disease (nonmalignant), of 200 with cancer of the colon and rectum and of 200 patients seeking treatment because

of hemorrhoids. Interestingly enough, the overall incidence of cancer in the family was much the same: for gallbladder disease 26 per cent; for cancer of the colon and rectum 30.7 per cent, and for hemorrhoids 29.6 per cent. The only conclusion which one legitimately may draw from these observations is that cancer is frequent and approximately 30 per cent of families give a history of cancer sufferers amongst their members.

THE PROBLEM OF GASTRIC CANCER

These facts afford evidence of the great importance of the problem presented by gastric cancer. This perplexing problem obviously comprises many factors, most of which have had considerable discussion. Several well-known surgeons, who in the estimation of their colleagues were authorities on the clinical aspects of the disease and who essayed to instruct others in the early manifestations of gastric cancer, recognized the signs of the disease in themselves too late to benefit by that therapeutic agent of which they themselves were masters. Among others are to be enumerated the names of Johannes von Mikulicz, W. J. Mayo, D. P. D. Wilkie and Martin Kirschner. The late R. D. Carman, well-known roentgenologist who contributed a useful sign to the roentgenologic diagnosis of gastric cancer, had a gastric cancer which was inoperable before he recognized the signs of the disease in himself.

This circumstance in itself suggests that there is no symptom complex by which the disease can be identified, a situation which a number of other particulars and occurrences corroborate. The absence of warning signs of approaching danger accounts in large measure for the circumstance that so many patients with gastric cancer are inoperable when they first consult their physician. The German poet Theodor Storm, who wrote "Immensee," which a number of us studied in earlier years, died of gastric cancer. He wrote a poem entitled "Beginn des Endes"[31] concerning his illness, which described well the insidiousness of gastric cancer.

Beginning of the End

'Tis but a prick, 'tis scarce a pain,
  Just felt, to which no name you give:
Henceforth it speaks again-again,
  Uneasy now you have to live.

If to complain you try—of what?
  You cannot put it into speech:
Within you say, "Indeed 'tis naught!"
  Henceforth it holds fast like a leech.

So seldom strange your world does grow,
  And quickly are you stript of hope,
Until at last you really know
  That with Death's shaft you cannot cope.

Storm died in 1888, seven years after Billroth had the first operative success with gastric cancer. The roentgen ray, discovered in 1895, has since become the most reliable means of diagnosing gastric cancer. While this agent even in expert hands is not infallible, it approaches a state of excellence achieved by only a few diagnostic agents. The problem is to get those afflicted with gastric cancer in the early stages to consult expert roentgenologists in time, so that surgical intervention will benefit a larger number of patients with gastric cancer.

It seems strange indeed that a malignant tumor can attain inoperable proportions in so active and useful an organ as the stomach without revealing early signs of its presence. I myself have removed from a young girl's stomach a hairball which produced a tumefaction on the abdominal wall, which outlined the stomach precisely. Yet after the bezoar was removed, the patient insisted that the sense of satiety after eating was acquired just as quickly as when that large hairball filled the gastric lumen! In other words, it is strange to what extent this organ, which can manifest signs of functional derangement readily in the presence of emotional or physiologic disturbances which have their origin elsewhere in the body, can accommodate itself to extensive local encroachment on its functions without revealing a trace of disorder.

This ability is peculiar to all hollow viscera; and inasmuch as the gastric lumen is so large, it is understandable that early detection by functional derangement in corporic or fundic gastric lesions is unusual, save as indicated by hemorrhage. It takes approximately 70 cc. of blood to produce a stool in which the presence of blood may be detected grossly. Two to 4 cc. of blood suffice usually to give a positive guaiac test in the stool.

How, then, is one to suspect the presence of a gastric cancer? Obviously one's primary concern is not the heedlessness and indifference of patients to their symptoms, though this item as well as the reaction of physicians to the complaints of patients is not without importance for the problem—one's primary concern, if one is to be realistic, must be with the circumstance that a gastric cancer may become inoperable before its presence causes any perceptible derangement of function.

Cutaneous cancers occur largely beyond the wrist line and above the collar line. Moreover, they grow slowly. The significance of a small blemish of the skin which fails to heal may not be appreciated immediately, but its very presence urges its owner or his friends or relatives to have something done about it. Even in cancers which are accessible to the examiner's hand but hidden from the sight of others early detection is by no means regular, and the frequency with which those who suffer from cancer of the tongue, breast, uterus and especially its cervix, vulva, penis, prostate and rectum come late for treatment is a matter of general knowledge.

To permit the recognition of a cancer, an area of induration, tumefaction or ulceration must be present. And how long have cancer cells been present to permit such an occurrence? Undoubtedly, the time interval is variable and is dependent largely on the rapidity of growth. In patients for whom I have performed what I regarded as a radical operation for cancer of the stomach only to learn subsequently that cancer cells were detected by the pathologist in the most proximal line of resection, it has been my observation that these patients usually remain asymptomatic for eighteen to twenty-four months. This interval of freedom from symptoms in such palliative gastric resections gives some indication of how long it takes a cancerous tumor which already has exhibited invasive qualities to grow and reassert itself.

The greatest hurdle to early detection of internal cancer is the absence of a reliable immunologic test for cancer. Such a diagnostic agency is the hope of every clinician who must wrestle with the intricate complexities of the recognition of cancer. And whereas such specific tests for cancer are well within the realm of achievement, there is little promise that such serologic tests will be available soon.

---

FREQUENCY OF GASTRIC CANCER

The death rate from cancer of the stomach in the United States is approximately 30 per 100,000 for the population as a whole. At the peak incidence of occurrence, which is between 400 and 500 for men between 75 and 80 years of age, only 1 man among every 200 to 250 will die each year of gastric cancer. There seems to be a fairly sharp rise in mortality due to gastric cancer in men at 55 and in women at 65 years of age. According to Kirschner[32] (1940) more than half the deaths from cancer among men in Germany are due to gastric cancer. And the studies of Dormanns[33] (1939) suggest that approximately 33 per cent of all cancer deaths in Germany are due to gastric cancer.

Both vital statistics and necropsy statistics are mortality records. They deal with the frequency of cancers among the dead, not the living. There is a certain concordance between the causes of death in these mortality records. In the main, autopsy records are perhaps weighted with more than a representative number of serious illnesses which demand hospitalization, to which category of disease cancer belongs. Yet the greater accuracy of diagnosis at autopsy offsets in large measure the disparity of uneven distribution of disease present in autopsy statistics.

Frequency of Cancer in Autopsy Records

	No. of Autopsies	Percentage of All Deaths Due to Cancer		Percentage of Cancer Deaths Due to Gastric Cancer	
		Males	Females	Males	Females
Berman[34] (1944) (Minnesota 1933 1938) all ages............	11,543	17.0	19.0	...	...
Dormanns[35] (1937) (1925 1933) 42 German institutions; all males over 20 years.........	124,827	17.7	....	6.0	...
Lummerich[36] (1936) (1925-1934) Hamburg, Germany; men and women over 20 years	10,566	17.4	20.7	6.7 8.8 (50-70)	4.3 5.0 (40-70)

Berman[34] (1940) examined the autopsy records of the Department of Pathology of the University of Minnesota between 1933 and 1938, during which years 11,543 autopsies were performed. Berman found that 19 per cent of the deaths in females over 1 year of age was owing to cancer and that for males this figure was 17 per cent.

Dormanns[35] (1937) analyzed the causes of death in 124,827 autopsies performed on men over 20 years of age in forty-two pathologic institutes in Germany between 1925 and 1933. Of these deaths 22,139, or 17.7 per cent, were due to cancer; 33 per cent of all cancer deaths were caused by gastric cancer. Dormanns, however, included only carcinomas and excluded lymphoblastomas, brain tumors and sarcomas, which together constitute a rather large group. In Dormanns' series 6 per cent of all cancer deaths were due to gastric cancer.

Lummerich[36] (1936) examined the autopsy records of the Barmbeck Krankenhaus in Hamburg for the years 1925 to 1934. There were 10,566 autopsies done on men and women over 20 years of age, of which number 19.1 per cent died of cancer. The cancer mortality for women over 20 was 20.7 per cent; for men, 17.4 per cent. In Lummerich's series 6.7 per cent of all deaths in men over 20 years of age were from gastric cancer; in women this figure was 4.3 per cent. In women between the ages of 40 and 70 gastric cancer was responsible for 5 per cent of the deaths, and in men between 50 and 70, 8.8 per cent of all deaths were caused by gastric cancer. In other words, among women between 40 and 70 years 1 in 20 deaths was due to gastric cancer and among men, 1 in 12. (See the accompanying table.)

AN ATTEMPT TO FIND PRECURSORS OF GASTRIC CANCER

Together with colleagues in the Departments of Medicine, Pathology and Radiology, my associates and I began in July 1945 to scrutinize carefully all patients with demonstrated histamine achlorhydria (no free hydrochloric acid after three successive 0.5 mg. doses of histamine given at intervals of thirty minutes) in men over 55 and in women over 65. Since Jan. 1, 1946 men and women past 50 years of age have been accepted for study. All such patients found to be achlorhydric, whether men or women, have been subjected to careful roentgen studies and whenever feasible to gastroscopic examination. During this interval there was a registration in the outpatient clinic of the University Hospitals of 1,949 eligible persons (from the point of view of age). Of this number, 1,070 patients (649 men and 421 women) were submitted to fractional gastric analysis with histamine. Only 205 patients were found refractory to all three doses of histamine; 62 additional patients remained achlorhydric after two doses and 34 to a simple injection of histamine. In all there were 301 achlorhydric patients available for study. To this group of cases an earlier series of 85 additional cases studied by Dr. Macnider Wetherby of the Department of Medicine was available for continued study. In addition, 79 patients with known pernicious anemia were also available to us.

Among these 464 patients who were achlorhydric to histamine, 15 patients with polyps have been found—the most fruitful observations of the study. In a large percentage of the patients coming to this clinic with carcinoma of the stomach, the disease has already been diagnosed before their arrival, or the presence of such a lesion is suspected by the first observers to see the patient in the outpatient clinic. In consequence, during the fifteen month period that this study has been under way, only 3 undetected gastric carcinomas have been uncovered. Only 1 of these was early. Moreover, this patient's lesion was missed by roentgen examination; he also had a cecal cancer, and when operative intervention was undertaken by the resident, Dr. Arnold Kremen, the gastric lesion was found. Both lesions were dealt with successfully at the same operation. A similar occurrence happened with a rectosigmoidal cancer in a patient in whom no search for a gastric cancer had been made preoperatively. This patient, aged 75, had extensions of the lesion into a loop of terminal ileum. A fairly large gastric cancer was a surprise finding. Three simultaneous resections were carried out successfully for the patient. The third patient, and the only isolated instance in this group of patients in which the detection of a gastric cancer was due solely

to study suggested by the presence of achlorhydria, was a large man of 73 with hypertension, who succumbed after operation from hemiplegia. The tumor was large, and the operation, undertaken by Dr. David State, was essentially a palliative resection.

This is not the record of an accomplishment which justifies enthusiasm. The greatest promise of the study so far appears to be the continued observation of the patients found to have polyps and the search for gastric polyps in other achlorhydric patients. It is an interesting observation that patients with gastric polyps are almost uniformly achlorhydric, a circumstance to which Brunn and Pearl [37] (1938) have directed attention.

Among the 140 patients with gastric cancer, whose records have been reviewed in this study by Drs. Robert A. Hebbel and David Gaviser, only patients with polypoid cancer were uniformly achlorhydric. The incidence of achlorhydria in ulcerative and diffuse cancer (Borrmann's classification) varied between 55 and 67 per cent. The polypoid variety, the type of gastric cancer with the most favorable prognosis, is unfortunately uncommon, being observed only 5 times among the 140 patients.

St. John, Swenson and Harvey [38] (1944) subjected 2,413 patients over 50 years of age to a brief fluoroscopic survey of the stomach. In this group of patients, 2 silent gastric cancers and 1 lymphosarcoma were found, an incidence of unsuspected gastric malignancy of 1.24 per 1,000 patients. No gastric polyps were observed in this study. Dailey and Miller [39] (1945) reported a series of 500 patients subjected to barium examination of the stomach. These examinations were performed on presumably normal men who were free from digestive complaints and were over the age of 45. Three gastric lesions were found: a benign gastric ulcer, a polyp and antral gastritis.

DISPOSITION OF PATIENTS IN WHOM DIAGNOSIS OF GASTRIC CANCER IS MADE

In the light of present knowledge, the only worth while treatment for patients with gastric cancer is surgical extirpation. The most radical surgery with the lowest mortality is the best surgery. William J. Mayo, a keen exponent of gastric surgery, gave the surgery of gastric cancer in this country an early impetus, which practice should have had wider emulation in other clinics. The accomplishments of surgery in gastric cancer during the past decade have been real. The lament of surgeons is that so many patients come late. The fundamental clinical problem in gastric cancer is not improvement in gastric surgical procedure, though considerable opportunity for improvement exists there, too. The problem which demands solution in the management of gastric cancer is earlier recognition.

Surgeons schooled and experienced in the disciplines of visceral surgery can resect the stomach for cancer with risks which are not far in excess of those assumed by patients undergoing resection for benign ulcer. Obviously, the number of patients who are advanced in age and in poor physical condition together with the more aggressive character of the surgical removal with reference to lymph nodes and adjacent structures does increase the risk. It was not so long ago that the operative mortality from total gastrectomy was approximately 50 per cent. However, surgeons have learned to deal more effectively with the technical details of suturing the esophagus to the jejunum and have reduced that risk considerably. A technic which I have used to advantage is to suture the mesenteric border of the jejunum behind the esophagus. This maneuver permits the placement of two rows of interrupted silk sutures which anchor the posterior wall of the esophagus firmly against the wall of the jejunal segment. The anastomosis then may be made at the antemesenteric border. Employment of the anterior peritoneal flap overlying the subdiaphragmatic esophagus as described by Lahey [40] (1928), Kirschner [41] (1933) and Jones [42] (1945) is utilized to cover the suture line anteriorly.

In this clinic the closed anastomosis has been employed routinely in all resections of the gastrointestinal canal since 1938. It affords the greatest opportunity for performing the operation in an aseptic manner. All these items have been described previously [43] and will not be repeated here.

The importance of excision of the greater omentum has been stressed particularly by Groves [44] (1910) and Finsterer [45] (1930). An equally important item is complete excision of the gastrohepatic omentum above the lesser curvature. By trimming the avascular and normally somewhat diaphanous membrane down from the hepatic edge and isolating and tying the left gastric artery just after it leaves the celiac axis, the entire lymph-node-bearing area of the lesser curvature can be removed. Near the esophageal juncture this procedure is carried out most readily in a retrograde fashion. By separating the leaves of the gastrohepatic omentum near the site at which the left gastric artery meets the lesser curvature, the upper attachments of the gastrohepatic omentum can readily be removed up to and including that portion attached to the esophagus. After the gastric wall is bared between the leaves of the gastrohepatic omentum where the branches of the left gastric artery enter it, a long curved hemostat or dissector can be run up this groove. A counter opening is made just over the subdiaphragmatic esophagus, and the remnants of the gastrohepatic omentum are easily removed from the gastric wall. This maneuver removes the entire blood supply of the lesser curvature, leaving the residual gastric fragment dependent on the small gastric arteries which come from the splenic or the left gastroepiploic artery.

Direct extension of the cancer into adjacent organs such as the pancreas, the left lobe of the liver and the transverse colon necessitates consideration of removal of the segments of tissue involved—extensions of the operation for gastric cancer which are fully justified in otherwise suitable cases. Moreover, lymphatic extensions into the transverse mesocolon are seen now and then, a circumstance which may suggest that the excision of the entire transverse mesocolon together with the spleen is the wisest procedure. For extensions in the head of the pancreas, unfortunately this principle of operative procedure would frequently demand performance of the Whipple operation, a rather formidable enlargement of the operation for gastric cancer.

One of the extensions of gastric cancer which is most difficult to deal with is the excision of adherent lymph nodes in juxtaposition to the common biliary duct, hepatic artery and portal vein.[7] By removing the peritoneum overlying these structures and by isolating and dividing the gastroduodenal artery, the hepatic artery may be displaced upward and to the left, permitting at least partial separation of these structures and removal of involved lymph nodes.

Palliative gastric resection in the presence of hepatic metastases is fully justified. The palliation achieved thereby averages in our experience about fifteen months. For hepatic metastases from primary rectal or colic cancers, however, removal of the local lesion has resulted in extending the life of a few patients two or three years and longer. This circumstance suggested the possibility of excising the hepatic metastases in patients undergoing colic resection for cancer, an operative procedure which now has been carried out in several patients. The problem of hemostasis in resection of the liver is not difficult, and, knowing the great capacity of the liver to regenerate, the feasibility of extensive hepatic resections as well as reoperation for the removal of additional previously undetected hepatic metastases is within the range of possibility.

Whereas surgeons can perform these operations, mere discussion of the magnitude of the undertaking suggests definitely that a greater salvage of life from gastric cancer is to be obtained by having the patients submit to operative intervention before it is necessary that the resection be so radical.

The experience of this clinic suggests that these radical operations for gastric cancer, including total gastrectomy, can be performed at a reasonable risk. For the past four years, during which time 160 resections (including total gastrectomies) were performed, the hospital mortality was 8.1 per cent. In 1945 there were 62 resections (including 9 total gastrectomies) with 3 deaths (4.8 per cent mortality).

The resection rate of patients operated on for gastric cancer in this clinic has been approximately 90 per cent for several years. In other words, palliative resections are being undertaken in a number of instances. In consequence, the per cent of long survivors after operative intervention will probably not be as great as that in clinics where resection is confined largely to cases with a favorable outlook. My colleague, Dr. David State, is compiling the late results in patients operated on for gastric cancer in the last ten years. The follow-up, though not complete, suggests definitely that a radical operative procedure holds out real promise to those who have gastric cancer.

Heretofore, many surgeons have performed a 95 per cent resection in many patients in whom total gastrectomy would have been a better operation for cancer—and solely because the subtotal operation is a safer procedure. With improvement of the mortality score of total gastrectomy, and with more consistent performance of a complete operation for gastric cancer which deals satisfactorily with the problems of the lymph nodes and local extension, the number of long survivors after operation will increase considerably. The development of a technic of esophageal resection holds out hope for those patients whose lesions involve both the fundus of the stomach and the distal end of the esophagus, a neoplasm which up until a few years ago was regarded as inoperable. The surgical management of these lesions is primarily a problem of the esophagus and has not been dealt with in this article.

THE NEED FOR REAWAKENING INTEREST IN THE EARLIER DIAGNOSIS OF CANCER

The proportions to which a gastric cancer may grow without causing symptoms have already been indicated. Moreover, patients with cancers which affect organs within reach of the examiner's hand as a group also seek treatment late. There is undoubtedly a time when every maligant tumor is a local lesion. In approximately 25 per cent of patients with gastric cancer coming to autopsy, the disease involves only the stomach and the adjacent lymph nodes. In any cancer involvement of the lymph nodes influences the prognosis in a distinctly unfavorable manner. The lapse of time from the assumption of histologic characteristics of cancer by mucosal or epithelial cells to the invasion of the normal submucosal or subepithelial tissue is undoubtedly a variable phenomenon. In the main, gastric cancers are of a high grade of malignancy and probably demonstrate invasive features early. However, even for gastric cancer Mallory[27] (1940) has shown that such tumors may remain as carcinomas in situ for rather long intervals of time.

The interest of the public in cancer is real. Many persons, perhaps some physicians among them, believe that a Cancer Commission with authority to draft competent workers with research experience—such a group to pool their knowledge and talents—could with adequate funds untie the gordian knot of the problem of cancer in a period of five to ten years. Without question such a planned and coordinated attack on the problem of cancer would bring to light many new facts. The process of accumulating new facts is slow. The construction of an idea or an approach to a problem by experienced persons in possession of the assembled facts progresses directly with the availability of known facts. If they are few, the process will be as slow as constructing a house from bricks when only an occasional brick becomes available at periodic intervals.

Such appears to be the situation in the experimental approach to the problem of cancer. Distinct progress is being made from year to year. Until the stock of available information is greater, it cannot be expected that a preventive agent against cancer or a revolutionary therapeutic agent to combat established cancer will be found quickly.

The public looks to the members of the medical profession for intelligent guidance in matters of health. The public is willing to spend unlimited funds to conquer the scourge of cancer. The important contributions of scientists to the winning of the war has the public wondering whether use of the same tactics would not soon end the tyranny of cancer. Certainly cancer research should continue with unremitting vigor. But until many more facts concerning cancer are known it is unreasonable to expect that the experimental approach to the problem will quickly turn up a cure for cancer.

However, it is known that 1 woman of every 5 past 40 years of age is destined to die of cancer and that 1 of 6 men past 50 similarly will die of cancer. This is not a pleasant prospect, especially when one realizes that for a large number of cancers, especially those of the digestive tract, which constitute more than 50 per cent of all fatal cancers, the problem is primarily one of recognition and not of cure. In other words, granted early diagnosis, a large number of cancers are curable.

It is known that a large per cent of persons will have cancer and die of it. The only unknowns are: (1) which persons, (2) in what organ and (3) when?

Let us consider the case of the mouse. The average life span of the mouse is approximately sixteen months or four hundred and eighty days. In cancerous strains of laboratory mice in which cancer of the breast develops, tumors begin to make their appearance ten to twelve months after birth, or when about 60 to 75 per cent of the life span of the mouse has been lived.

Approximately 90 per cent of fatal cancers are observed in persons over 40 years of age. In the female there is a definite increase in the mortality due to cancer at 40 years of age. The life expectancy of persons who have already reached the age of 50 is approximately twenty years. In women when approximately 60 per cent of the life span has been spent and in men when 70 per cent of the allotted time has run out cancer is most likely to make its appearance. Workers in cancer who deal with mice examine the mice once a week for evidence of tumors. Should not physicians observe the same care in examining men and women for evidences of cancer as experimental workers do in caring for mice?

Cancers in situ perhaps will not often be recognized in the stomach. Yet periodic examination of all men and women who have reached "the cancer years" undoubtedly will make an important contribution to earlier recognition of cancer.

Will the public which is so keenly interested in a cure for cancer be cooperative in this effort? There is need for Cancer Detection Clinics set up at strategic places with competent specialists in the various branches of medicine and surgery. Moreover, there is need for the cooperation of all men and women in attending such clinics, when established, approximately three times a year. If the support in funds and of the public in attendance on such clinics is forthcoming, I believe that it will represent the best use of the available knowledge in dealing with the problem of cancer. The promise of the future is in the discovery of new facts which will lead to new ideas and a final solution of the problem of cancer. One must plan for one's own generation, however, and for one's children and grandchildren, as well as for generations yet unborn. To that end, one must be realistic and deal with situations as they are and not with situations as one would have them.

The worth of the Cancer Detection Clinic remains to be proved. But granted adequate financial support and backing by the members of the medical profession and cooperation by the public, I believe that the establishment of such a clinic will be an important step toward bringing the menace of cancer under control. Until this venture has proved itself in a factual manner, the unlimited support of the undertaking by any agency cannot be expected. Given an adequate opportunity, however, I am convinced that a few "pilot plants" will not only be able to explore the province of Cancer Detection Clinics but also to prove their worth.

It may seem somewhat anomalous that a surgeon, from whom expressions might be expected concerning the benefits of his specialty to patients with gastric cancer should belabor the item of diagnosis. In contemplating the achievement of surgery in wrestling with the problem of gastric cancer—and I am certain that many share this impression—I feel that it is much as though one has been at work enthusiastically and feverishly in the back yard at a huge woodpile. When one glances up to survey what remains to be done, startled by the small proof of his efforts and at the same time noting that the sun is well past the meridian, one realizes the futility of merely whittling away at a constantly enlarging woodpile. Moreover, the better wood is at the fresher end of the pile. I would not depreciate the accomplishment of the surgeon; on the contrary, if in every phase of activity relative to gastric cancer there had been an improvement similar to that which has occurred in its surgical management, the surgeon would have far less occasion for dissatisfaction with his accomplishment.

If one reviews the progress that has been made with the problem of gastric cancer since the International Conference on Cancer was held in London in 1928, the conclusion is inescapable that the contribution of surgeons in extending the benefactions of surgery to an ever increasing number of patients constitutes the most important advance during this period, however small that gain appears to be when measured against the broad background of the entire problem of gastric cancer. Yet the distinguished Scottish surgeon, Wilkie,[46] who spoke at that conference on "Early Diagnosis and Treatment of Gastric Cancer" and who has since died of a gastric cancer diagnosed too late, said on that occasion, "The technique of the operation (for gastric cancer) has been raised to a standard which leaves little to be desired." If during the next eighteen years as important progress can be made in the early detection and recognition of gastric cancer as has been made since these words of Wilkie's were spoken, considerable acceleration of momentum will have been lent to the solution of the problem of gastric cancer.

The detection of cancers of the alimentary tract which are out of reach of the examining finger will not be easy even in Cancer Detection Clinics. But with careful interrogation of patients who appear for examination, together with hemoglobin determinations, a study of the stool for blood, an assay of the gastric juice for free hydrochloric acid, roentgen studies and gastroscopic studies in suitable cases, certainly gastric cancer will be diagnosed earlier with greater frequency than now. Moreover, such an approach to the problem of gastric cancer holds out far greater promise of improvement in the results of management of gastric cancer, for surgeons will then have an increased opportunity to make a better showing with the problem of gastric cancer.

Indifference and inertia are far more to be feared than the hazard of stirring up phobias of cancer. When the achievement of the surgeon in the treatment of cancer is better the public will fear the disease less. The relatives of patients for whose cancer I have been able to do little frequently ask how they can avoid the pitfall of seeking medical advice too late. My reply is: Go to your physician and be examined three or four times a year. To such a reply, from the wife of a patient for whom I had performed a palliative gastric resection for gastric cancer, I received a tearful letter which said in part: "I wish I could do something to awaken all doctors to the importance of the menace of cancer of the stomach. My husband saw five well-known men in this community during the past year.

---

[46] Wilkie, D. P. D.: Early Diagnosis and Treatment of Gastric Cancer, International Conference on Cancer, London, Bristol, John Wright & Sons, 1928.

They examined him together with samples of his blood and urine. All of them said he was sound as a dollar. All he needed was a good rest. Not one suggested that he should have an x-ray examination of his stomach!"

The story of the insidiousness of gastric cancer is well told in this woman's letter. Only the coming of Cancer Detection Clinics, staffed by specialists in the whole range of medicine and strategically located, will reduce such occurrences to a minimum.

SUMMARY AND CONCLUSIONS

Cancer ranks only next to cardiac disease as a cause of death and takes an enormous toll of life. Approximately 150,000 persons die annually of cancer in this country, and there are probably at least 500,000 patients suffering from cancer at any one time in this country. Cancer is therefore a concern of the public health of the people of great importance.

The most frequently observed malignant growth is gastric cancer, which accounts for 25 to 40 per cent of all deaths due to cancer in countries with a population such as that of the United States, in which more than 20 per cent of the people are over 50 years of age. Cancer is statistically an important cause of death at every age, but its incidence increases significantly with advancing years. Autopsy figures suggest that in men over 20, 6 per cent of all deaths are due to gastric cancer; and in men between 50 and 70 years, 8.8 per cent of deaths are caused by gastric cancer. In women 4.3 per cent of deaths at autopsy in patients over 20 years of age are due to gastric cancer, and 5 per cent of all deaths in women between 40 and 70 years are caused by this disease.

The tragedy of the problem of gastric cancer is that too many patients come to the physician with the disease so late that surgery, the only worthwhile therapeutic agent, can hold out little hope. For the patient whose disease is local, surgical intervention promises a 20 to 25 per cent rate of cure. Inasmuch as the mortality of radical operation for gastric cancer in experienced hands is approximately 5 per cent, granted the early recognition of the disease the present gloomy prospect of gastric cancer could be much brighter.

The problem of gastric cancer is essentially one of earlier detection of patients in whom the lesion is developing. One cannot await the complete evolution of the clinical symptoms. If gastric cancer is to be diagnosed consistently in earlier stages than is done at present, patients of advancing years should be scrutinized periodically for evidences of cancer.

The establishment of Cancer Detection Clinics, staffed by specialists, affords the best promise of the early recognition of cancer. Women over 40 and men past 50 should report regularly to such clinics.

The solution of a difficult problem such as this demands the following:

1. Members of the medical profession must look at the problem realistically and learn to know all the facts bearing on it.
2. They must constantly enlarge their knowledge of the field by vigorous research and clinical investigation.
3. All available resources must be combined to lend pursuit of the inquiry the greatest promise of solution.
4. The solution of the problem must envisage an interest in the problem as it relates to the present generation as well as to those yet unborn.

The greatest hope for the present with reference to the cancer problem lies in the Cancer Detection Clinic. New discoveries as the result of a coordinated and energetic research program constitute the hope of the future.

On the occasion of the London International Conference on Cancer (1928) King George V[47] said: "I note with interest that your object is research, both into the cure and causes of cancer. No doubt in the last resort the discovery of the cause is the only certain and absolute means of cure. But I am glad that you have not ignored the practical side of the problem. Remembering the thousands of sufferers from cancer, I feel that if your discussions lead to advance in diagnosis, treatment or even palliation of the disease, this Conference will have justified itself and earned the gratitude of mankind."

Those well-chosen words of King George V spoken eighteen years ago at a general conference on cancer state the present day problem of gastric cancer very clearly. The immediate primary concern of the physician must be to strive to recognize gastric cancer earlier.

DISSEMINATED LUPUS ERYTHEMATOSUS AND DIFFUSE SCLERODERMA

GEORGE BAEHR, M.D.
and
ABOU D. POLLACK, M.D.
New York

In 1942 together with Dr. Paul Klemperer we[1] employed the term "diffuse collagen disease" to indicate that in disseminated lupus erythematosus and in diffuse scleroderma, the basic morphologic changes were found in the connective tissues. Similar but less conspicuous changes in the connective tissues are observed also in rheumatic fever, periarteritis nodosa, rheumatoid arthritis, thromboangiitis obliterans and serum sickness. It must be emphasized that in each of these diseases this collagen degeneration may lead to conspicuous alterations in the walls and lumens of blood vessels, in the endocardium, pericardium and pleura, in the articular and periarticular tissues and in the dispersed connective tissues (mediastinum, retroperitoneum and subcutaneous tissues). Thus, in all the diseases of this group, one may encounter clinical evidences of vascular involvement, pericarditis, pleuritis and arthritis.

In recent years much emphasis has been placed on the fact that fibrinoid degeneration of collagen and the various vascular and visceral lesions to which it gives rise represent the "common denominator" of this group of diseases.[2] On such grounds it has been implied that the diseases are related or that they have a somewhat similar cause.

Fibrinoid degeneration of the connective tissues of the blood vessels, endocardium and synovial membranes can be induced experimentally by repeated intravenous injections of heterologous serum or of other protein or bacterial antigens.[3] From this, it has been urged that all those diseases in which fibrinoid degeneration of collagen is prominent may also be founded in allergy or para-allergy.[4] The purpose of this paper is to reconsider the clinical and pathologic manifestations of disseminated lupus erythematosus and diffuse scleroderma and to reexamine the evidence regarding their possible relationship with other "collagen diseases"[5] and more specifically with allergy.

DISSEMINATED LUPUS ERYTHEMATOSUS

Clinical Features.—It is now generally agreed that the erythema on the bridge of the nose and cheeks and other areas of the skin exposed to the trauma of strong sunlight and wind is the visible but not the primary manifestation of the disease.[6] Nor is this lesion responsible for the other alterations in the viscera. In fact, the cutaneous lesions for which the disease was named almost a hundred years ago may be absent throughout the entire course or may appear only in the terminal stage or during acute exacerbations of the illness.[7] Disseminated lupus is a prolonged febrile disease of the body as a whole, which, in the absence of cutaneous manifestations, may superficially resemble rheumatic fever and rheumatoid arthritis.

If the cutaneous rash has not made its appearance, the differential diagnosis may be extremely difficult. As in rheumatic fever and rheumatoid arthritis, weakness and a prolonged irregular fever are the most characteristic symptoms. Arthralgia and even arthritis are present from time to time, but are seldom as conspicuous as in the other two diseases. Suspicion of disseminated lupus erythematosus is warranted in a young woman with a prolonged undetermined fever, with or without migrating articular pains, if there is a consistent leukopenia and if red blood cells are found in the urine. During exacerbations of the disease, pyrexia may be high and, again as in rheumatic fever, there may develop in the patient the symptoms and signs of acute pericarditis or pleuritis or even abdominal pain.

The exacerbations, like the periods of remission, occur without obvious cause. They are usually marked by the appearance of albumin and red blood cells in the urine or, oftener, by the eruption or efflorescence on the bridge of the nose of erythematous macules, which tend to coalesce and spread in butterfly pattern over the cheeks. The rash may also extend to the chin, the superciliary ridges, the pinna and the V-shaped exposed manubrial area of the chest. The erythema may have a purplish tinge. Close examination with a hand lens often reveals superficial telangiectatic capillaries and petechiae. Erythematous macules of this type are observed in some severe cases also on the tips of the fingers and the toes, around the nail bed and scattered on the palms and soles. In extreme cases, erythematous areas may appear on the shoulders, elbows, knees, over the malleoli and, in fact, on any part of the body exposed to friction.

Generally speaking, during exacerbations erythematous patches, which appear on the mucous membranes, especially of the mouth, soon lead to shallow ulcerations and shortly proceed to healing. In this disease, unlike rheumatic fever, the lymph nodes are frequently enlarged. The spleen is seldom sufficiently enlarged to be palpable. Examination of the ocular fundi often reveals perivascular hemorrhages or fluffy exudates and occasionally, during exacerbations, circumpapillary edema. These retinal changes, possible manifestations of the widespread vascular injury, sharply distinguish lupus erythematosus from rheumatic fever and rheumatoid arthritis. The presence of leukopenia is always helpful in diagnosis. It is usually associated with moderate depression of hemoglobin, red blood cells, platelets and serum albumin. During intercurrent pneumonia or other secondary infections, it may be temporarily superseded by leukocytosis. During exacerbations of the disease the Wassermann test may become falsely positive or anticomplementary. Blood cultures are negative unless there is an intercurrent or terminal infection.

In this disease, in contrast to rheumatic fever, heart murmurs and the signs of congestive heart failure are absent or inconspicuous, and such murmurs usually disappear during remissions. When heart murmurs are audible during exacerbations it is difficult to ascribe them to verrucous endocarditis, for they may as readily be due to pyrexia, to anemia or to the effect on the myocardium of a long debilitating illness.

Pericarditis revealed by a friction rub is not uncommon during periods of exacerbation. Substernal pain may in some instances be due not to pericarditis but to involvement of the connective tissue of the mediastinum. For this reason, dysphagia may be an occasional complaint. The electrocardiogram is usually normal except for low voltage, characteristic of any prolonged debilitating illness. When pericarditis occurs, the electrocardiogram may then present the characteristic changes. Dry pleurisy is frequently observed during exacerbations. More infrequently there are episodes of abdominal pain which may be due to peritoneal serositis or to involvement of the retroperitoneal connective tissues.

Usually the disease runs its course to a fatal issue after a variable period, which may be weeks, months or years. Complete or partial remissions may last for months or years. A patient now under our care in an exacerbation has had the disease for more than nine years. We have seen several patients recover completely after a long and irregular period of illness, which at times seemed as if it would end fatally. One of the worst has now been well for eight years. We do not know the cause of the disease or the reason for recovery. However, although remissions are common, permanent recovery is unusual.

The most striking characteristic of disseminated lupus erythematosus is its predominant occurrence in young women; it may also occur in childhood. In our clinical material, 95 per cent of the patients were females. The few young males having the disease presented no sexual or endocrine abnormalities.

Pathologic Features.—It is not the purpose of this paper to describe in detail those changes in the tissues which are the morphologic expression of the disease, disseminated lupus erythematosus. This we have already done elsewhere.[8] At autopsy the gross examination is often disappointing, except when one encounters the characteristic endocardial lesions of Libman and Sacks.[9] It is for the microscope to reveal the connective tissue changes in the walls of small arteries, in the renal glomeruli, the skin, the mediastinum and in the subendothelial connective tissues of the endocardium, epicardium and other serous membranes. In the affected areas there is swelling of the connective tissue ground substance and fibrinoid degeneration of the collagen fibrils. The latter become swollen, straightened and often matted together into conglomerate masses of homogeneous refractile material which is intensely eosinophilic. In the most advanced phase, the connective tissue may become completely necrotic and basophilic fragments of nuclei, cytoplasm and fibrils become set in the eosinophilic ground substance.

In these previous publications [illegible] disease of the connective tissues," and "diffuse [illegible] are, of course, only convenient formulas not to be interpreted literally. We deal not with "disease of the connective tissues" but with disease of unknown nature in which the most important structural manifestations are found in the connective tissues The modern conception of scurvy may offer a helpful analogy—a disease in which the deficiency of ascorbic acid results in failure to achieve the normal colloid state of the ground substance of the connective tissues (Wolbach, S B).

[6] (*a*) Baehr, G ; Klemperer, P , and Schifrin, A Tr. A Am Physicians **50:** 139, 1935 (*b*) Baehr, G , in Cecil, R L Textbook of Medicine, ed 6, Philadelphia, W. B Saunders Company, 1946

[7] It is important to emphasize that an erythematous blush on the bridge of the nose and cheeks in the absence of fever and other clinical evidences of a serious systemic illness is not sufficient to warrant a diagnosis of disseminated lupus erythematosus, for it may be observed in a variety of other conditions

When this fibrinoid swelling involves the basement membrane of the glomerular capillaries, the glomerular loops appear discrete and rigid, presenting what we have called a "wire loop" appearance.[6a] In other glomeruli in which the process is even more severe, the swollen collagen masses in some loops may undergo necrosis and present a superficial resemblance to embolic glomerular lesions of subacute bacterial endocarditis. When small arteries in the viscera appear necrotic, either totally or in their intimal, medial or adventitial coats, it is because the connective tissue cement substance which binds the intimal and muscular elements has suffered fibrinoid necrosis. The swollen fibrinoid ground substance may bulge into the lumen of the affected artery and, in association with desquamation and degeneration of the overlying endothelium, completely occlude the vessel. In other words, the vascular lesions in this disease occur by virtue of changes in the connective tissue substrate of the affected vessels.

Similar areas of fibrinoid degeneration in the subendothelial connective tissue of the epicardium are responsible for pericarditis; of the pleura, for pleuritis; of the peritoneum, for perisplenitis or perihepatitis. In the subendothelial connective tissue of the cardiac valves or in the endocardium of the auricles or ventricles, areas of swollen, eosinophilic altered collagen may lift up the endothelium and extrude above the surface to form coarse nodular verrucae (Libman-Sacks form of endocarditis[9]). Such vegetations on the valves or walls of the heart are to be seen macroscopically in 40 per cent of the necropsies. These verrucae are free of bacteria. One third of our cases showed a terminal bacterial infection of older verrucae, but the larger destructive lesions of bacterial endocarditis were not encountered. Aschoff bodies were not present in any of the hearts.

In the cutis, fibrinoid degeneration of the connective tissue and vascular lesions are not always prominent. However, the dilatation of capillaries and the escape of blood from them suggests a profound damage to the connective tissue matrix which supports these capillaries.

The dispersed connective tissues of the mediastinum, the retroperitoneum and the synovial tissues often exhibit fibrinoid degeneration.

Around the central arteries of the spleen, there is frequently found a collar of concentrically layered, sclerotic, connective tissue fibers. Occasionally this mantle may be so thick that it can be recognized grossly. This is the only site in which augmentation and sclerosis of the connective tissue obtains, rather than degeneration.

In addition to nonspecific hyperplasia, the lymph nodes may present small or large areas of necrosis (in the past mistaken for caseous tuberculosis).[10]

While it may be said that widespread changes in the connective tissues of the body represent the morphologic facet of disseminated lupus erythematosus and that these tissue changes frequently reveal themselves clinically as vascular lesions (e. g. cutaneous eruption, hematuria or vascular lesions of the ocular fundi), these changes are by no means uniformly observed. It must be remembered that the described changes in connective tissues are not uniform in each case. Most remarkable are the patients who die in what seems to be a profound toxic state. None of the conventional causes of death can be ascribed. There is neither cardiac nor renal failure. There is no obvious fatal cerebral disease. As a matter of fact, we have had the experience of the rejection by the Municipal Health Department of the diagnosis of disseminated lupus erythematosus written on a death certificate as the cause of death. "People do not die of lupus erythematosus." But they do. And in some of the postmortem examinations performed on these cases, but little change may be found in the viscera.

We are dealing, then, with a disease which may express itself morphologically in terms which are today recognizable only as fibrinoid degeneration of the connective tissues. This is but the structural symptom of the disease, whose essential nature is yet to be disclosed. Unfortunately, this has led to the dubious logic that since experimental hypersensitivity also produces fibrinoid degeneration of connective tissue, any disease in which fibrinoid degeneration of connective tissue is prominent must be allergic in origin.[2b]

DIFFUSE SCLERODERMA

This disease resembles disseminated lupus erythematosus in the widespread changes affecting connective tissue throughout the body. Like lupus, the cutaneous manifestations begin on the periphery, on the hands and feet, the bridge of the nose and cheeks, but they may then extend slowly and inexorably to involve all parts of the face, the extremities and even the trunk. The fingers first become stiff and the mouth puckered. The skin becomes smooth, hard and tight so that it cannot be lifted from the deeper structures, a picture that is never seen in lupus even if the condition has been present for years.

Although arthritis occurs in some early cases of diffuse scleroderma, more commonly the victims have previously been sufferers from attacks of vascular spasm in the hands, resembling Raynaud's phenomena. Low grade fever may at times be present without obvious intercurrent infection, although usually the temperature is normal. After periods of exacerbation and sometimes remission, death ensues following years of progressive debility.

The peculiar sclerosis of the skin gradually results in more or less complete immobility of the joints of the fingers, hands, maxilla and sometimes even larger joints. Partly due to the complete immobility of the hands and fingers in a claw position, but probably more because of interference with circulation through the digital arteries, the phalanges undergo extreme rarefaction, and their peripheral ends may atrophy to mere points. Meanwhile, the degenerated and fibrosed periarticular tissues of the phalangeal joints may become heavily infiltrated with lime so as to form large periarthritic tophi. Broad areas of brownish pigmentation often develop, especially on the dorsum of extremities.

[10] Ginzler, A. M., and Fox, T. T.: Disseminated Lupus Erythematosus, Arch. Int. Med. **65**: 26 (Jan.) 1940.

In the skin, areas of fibrinoid degeneration may be seen microscopically, but the predominant change, even from the start, is a diffuse sclerosis of the epidermal and even subcutaneous connective tissue. The similar sclerotic process in the connective tissue of the esophagus may interfere seriously with its motility.

Clinically, we can see little resemblance between diffuse scleroderma and disseminated lupus erythematosus, nor has the former the characteristic female predominance of lupus. Their resemblance is rather in the fact that both diseases involve the connective tissue of the entire body and, although sclerosis is characteristic of scleroderma from the start, fibrinoid degeneration also occurs. This fibrinoid degeneration of collagen can be observed in the walls of small arteries, as Masugi [11] first reported. The pathologic changes in the arteries, in the subendocardial and epicardial connective tissue and in the glomeruli observed in diffuse scleroderma are identical with those which we have described in disseminated lupus, including the "wire loop" lesions and focal necrosis of glomerular tufts.[12]

ALLERGY AND SERUM SICKNESS

Gerlach [13] described fibrinoid degeneration of collagen fibrils in the Arthus phenomenon, and he and others have since regarded it as an essential feature of hyperergic inflammation. This form of connective tissue alteration has been frequently observed in animals which have been sensitized by repeated intravenous injections of bacterial or heterologous serum proteins.[14] Such experimental observations have been repeated most recently by Rich [3c] who assumed that he had thereby reproduced the pathologic lesions of rheumatic fever. He also observed these lesions in serum sickness and other conditions associated with allergy.[3b] This is in line with the former theoretic conclusions of Klinge,[14] Roessle [15] and Jaeger,[16] who group rheumatic fever, periarteritis nodosa and even thromboangiitis obliterans in a common rheumatic category and regard them as different manifestations of an allergic or hyperergic state, chiefly because of the common occurrence of foci of fibrinoid degeneration in all these diseases and in experimental allergy. The most recent support for this conception comes from Teilum [2b] who has added disseminated lupus erythematosus to the rheumatic or pararheumatic group of diseases. He has assumed that all diseases with lesions showing fibrinoid degeneration are essentially of allergic character, and he has explained the different clinical and pathologic characteristics of these diseases by the theory that the connective tissue reacts somewhat differently to the various allergens.

The proponents of the allergy hypothesis are protected in their theory by the fact that the specific provocative agent is still unknown in all these diseases except thromboangiitis obliterans, which is thought to be related to tobacco smoking. However, against their hypothesis stands the fact that typical fibrinoid degeneration is commonly seen in the walls of arteries in malignant hypertension and that it can be reproduced experimentally in animals in whom arterial hypertension is induced by the Goldblatt experiment, artificial reduction in the blood supply of the kidneys. In such experiments there can be no question of allergy. Fibrinoid degeneration can also be reproduced by injection of organisms of low virulence and of chemical agents into connective tissue.[17] It may often be seen in the reacting connective tissue adjacent to a foreign body and in the base of a peptic ulcer.[18]

It must be remembered that connective tissue is the supporting and cementing framework of all the organs and tissues of the body, that it consists essentially of collagen laid down in fibrils and of a ground substance, and that it has only three basic ways of reacting to injury—by degeneration, fibrosis, cellular reaction or all three. Degeneration may be expressed as swelling of the ground substance, fibrinoid changes in the collagen fibrils and in the extreme stage as necrosis. Fibrinoid degeneration may occur in any type of connective tissue injury with or without fibrosis or cellular reaction, and in itself, as Klinge emphasized,[14] it is not specific for any one type of injury.

The occurrence of fibrinoid degeneration in the Arthus phenomenon, in serum sickness and after sensitization to bacterial or heterologous serum antigens is insufficient ground for the assumption that disseminated lupus erythematosus and diffuse scleroderma must be the result of a hyperergic state induced by an unknown agent. The hypothesis brings us no nearer to the discovery of the cause of these diseases. Furthermore, it is entirely unsupported by clinical evidence. In all our long experience with these diseases we have never encountered a lupus patient with eosinophilia, urticaria, asthma or any other clinical manifestation of allergy. This is in striking contrast to the observations in periarteritis nodosa.

PERIARTERITIS NODOSA

Clinically, there has long been little reason to doubt that many cases of periarteritis nodosa are examples of an allergic or hyperergic state, in which the pathologic effects are most conspicuously focused on the medium sized arteries.[19] Unlike disseminated lupus, the condition occurs in both sexes, with slight predominance in males. The disease is frequently preceded by attacks of urticaria, asthma or other clinical manifestations of allergy, and pronounced eosinophilia is commonly present in the acute phase. Finally, the condition can be readily reproduced in experimental animals by injections of a sensitizing antigen.[3b, c]

In periarteritis nodosa the degeneration of collagen is limited to the vessel walls, and it is always accompanied in the acute stage by a conspicuous cellular inflammatory reaction in the adventitia and media, in which the participation of eosinophils is noteworthy. We have observed perivascular infiltration of vessels in lupus erythematosus only where there was complete necrosis of an arterial wall. Although this occasional lesion may resemble periarteritis superficially, the cellular infiltrate contains no eosinophils. In lupus erythematosus the participation of vessels represents but one phase of a general involvement of the connective tissues of the entire body. On the other hand, in only 1 of our cases of periarteritis nodosa was degeneration of collagen found outside the cardiovascular system.

RHEUMATIC FEVER

In spite of the fact that fever and arthritis may at times be the only clinical manifestations of disseminated lupus erythematosus, thus making a differential diagnosis from rheumatic fever difficult, the two diseases are otherwise clinically dissimilar. Although in persons who have once had acute rheumatic cardiac disease there may sometimes develop disseminated lupus years later, we have not yet observed the simultaneous occurrence of these diseases. The leukopenia, the cutaneous and oral lesions, the retinal lesions, the clinical evidences of renal vascular injury and the almost exclusive female predominance of disseminated lupus erythematosus are not seen in rheumatic fever or in rheumatoid arthritis.

In rheumatic fever similar but much less extensive foci of fibrinoid degeneration of collagen are to be found, chiefly in perivascular spaces of the myocardium, in the subendothelial layers of the valves and only occasionally in the walls of arteries. In rheumatic fever the smaller foci of collagenous degeneration characteristically call forth a striking cellular response with the production of Aschoff bodies in the myocardium. In disseminated lupus there is little cellular proliferation in the affected areas of fibrinoid degeneration and we have never seen Aschoff bodies. If proliferating fibroblasts are encountered in the fibrinoid areas, they already exhibit striking degenerative changes. In rheumatism, especially in the cardiac valves, the proliferation of fibroblasts is progressive and almost from the beginning associated with the production of new fibrous tissue. Similarly, even in the most advanced stages of rheumatic fever, the process never affects the basement membrane of the glomerular capillaries; the wire-loop lesions and focal necrosis of glomerular loops, so characteristic of erythematous lupus, are never seen in rheumatic fever.

CONCLUSIONS

1. The connective tissues serve not only as a supporting and binding substance for all the other tissues of the body but also as the medium through which all humoral and metabolic exchange between the blood and other tissues takes place. They can react to injury in three basic ways: by fibrinoid degeneration or necrosis, by fibrillar augmentation or sclerosis, by cellular proliferation or by a combination of these changes.

2. Fibrinoid degeneration of collagen can occur both as a general or as a local expression of injury, in a variety of heterogeneous and dissimilar disease processes.

3. Fibrinoid degeneration of collagen is, therefore, not a pathologic process of sufficient specificity to serve as a reliable common denominator for the classification of disease. It certainly does not warrant the grouping of all such conditions into a common category of allergic diseases.

4. Disseminated lupus erythematosus and diffuse scleroderma have in common a similar morphologic expression; namely, fibrinoid degeneration of collagen and identical lesions of blood vessels, glomeruli, endocardium and the serous and synovial membranes. However, they are so dissimilar clinically that they seem related neither to each other nor to rheumatic fever, rheumatoid arthritis, serum sickness, periarteritis nodosa or thromboangiitis obliterans, in which similar collagen changes may occur as part of the pathologic process.

5. Acceptance of an allergic basis for these two diseases without other supporting evidence serves merely to discourage other avenues of investigation into their essential nature.

ABSTRACT OF DISCUSSION

Dr. Paul O'Leary, Rochester, Minn.: I agree with Dr. Baehr that disseminated lupus erythematosus and scleroderma do not have a common etiologic agent and that fibrinous degeneration of the collagen is an end result, not a specific pathologic reaction, and may result from the effect of various noxae in diseases that are quite dissimilar. Clinically dividing lupus erythematosus into the chronic, subacute and acute forms helps materially in prognosticating the course of the disease, because patients who have the acute type of the disease may die within a period of months. Occasionally those with the acute type may adopt the subacute form and may live for some time; in occasional cases they may assume the chronic form and remain as modified invalids for many years. It is well to repeat for emphasis a point which Dr. Baehr made, namely, that the cutaneous lesions are by no means an indication of the toxicity of the lupus erythematosus process, because even though the cutaneous lesions may be minimal the patient may die within a period of several months from disseminated lupus erythematosus. Therapeutic castration of women who have disseminated lupus erythematosus has been valueless in my experience. Also, disseminated lupus erythematosus, during its phases of activity, has never resembled scleroderma. However, I do believe the clinical picture of disseminated lupus erythematosus will frequently resemble that of dermatomyositis, in which one occasionally sees various manifestations of scleroderma. In patients with the chronic type of disseminated lupus, those who have obtained a remission, the ensuing generalized atrophy of the skin is often difficult to differentiate from the end stage of scleroderma, but otherwise I do not know of any other factor which these diseases have in common. Scleroderma with its various and sundry clinical manifestations is a symptom complex probably due to various agents. The end process of many diseases belies their etiologic basis.

Dr. George Baehr, New York: Since this is an audience of clinicians, I wish to emphasize again that the presence of a butterfly rash on the face is not sufficient evidence on which to base a diagnosis of the disease. Evidences of a constitutional illness must also be present, for an erythema at this location may be due to other causes. Furthermore, if clinicians only study patients referred to them by dermatologists, they will see only those that have the rash. If they keep in mind the fact that not infrequently the disease occurs without any rash and that throughout a long course there may be no rash until the terminal exacerbation, they will frequently recognize cases. At least one third of the patients that we have seen were observed and the disease diagnosed before the cutaneous rash appeared. A few ran their entire clinical course without a rash, and in 1 case which we studied over a prolonged period the rash was limited to the hands. On making the diagnosis of a patient without a rash, prolonged fever, decided debility, and red blood cells in the urine are evidences of the visceral lesions; leukopenia is also diagnostically significant. Vascular lesions are often visible in the ocular fundi, and they should be searched for regularly. The Wassermann test is often falsely positive, and it may fluctuate from negative to falsely positive and back again. Coburn and Moore thought this was due to the rise in euglobulin, but I doubt whether this can be the explanation, in view of its fluctuating variability. It has nothing to do with syphilis. Dr. O'Leary has reemphasized the importance of the sex predisposition. As I stated, more than 95 per cent of our patients were women. It has not been our experience that treatment with testosterone propionate or castration in females materially altered the course of the disease. Exacerbations and remissions in this disease are so common that it is difficult to draw any conclusions as to the result of such therapy. It is our impression that they have not been successful. We cannot ascribe the remissions that we have observed, sometimes long remissions over many years, to the use of extremely large dosages of testosterone propionate or radiologic castration. Similarly, there are no endocrine disorders to be observed in women, no menstrual disorders, although as a result of increasing debility or secondary anemia amenorrhea may develop symptomatically. Also, in men we have seen no evidence of endocrine disorder. We are obliged to conclude that the female predominance merely represents a sex predisposition and is not the essential factor. It is perhaps equivalent to the male redisposition for thrombo-angiitis obliterans.

Clinical Notes, Suggestions and New Instruments

RECTAL COMPLICATIONS OF EPISIOTOMY

WILLIAM B. MARBURY, M.D.
and
MILTON L. GOLDMAN, M.D.
Washington, D. C.

In the past year or two we have treated 3 patients who had ctal complications manifested soon after episiotomy. Two of ie patients had typical fistulae in ano, and the third had rectal iin but no definite fistula. A brief summary of their histories ill be given later.

Although rectal complications of episiotomy seem of minor importance, they are extremely annoying and are of great concern, especially since they follow the ordeal of childbirth.

An attempt was made to review the literature on the subject, but apparently little has been written, since only one such article was indexed at the Surgeon General's library. That article was by Dr. J. J. Corbett,[1] who in 1938 reported 6 cases of rectal fistulas which developed after episiotomy. Because of the paucity of reports, in spite of the fact that these complications are not uncommon, we will attempt to outline briefly the most probable causes and the treatment of these complications.

Undoubtedly, episiotomy has been a definite advance in that it prevents rectal injuries due to extensive lacerations of the perineum; however, the operation itself may cause certain rectal disorders such as perianal abscess, fistula in ano, rectovaginal fistula and painful scars.

ETIOLOGY

Most of the complications follow infection of the episiotomy wound. In a study of 2,987 consecutive episiotomies, Kretzschmar and Huber[2] stated that infections occurred in 2.5 per cent when silkworm-gut was used and in 1.3 per cent when catgut was used. Pain develops a few days after the operation; this is followed by redness, edema and tenderness of the wound, which eventually ruptures and drains frank pus, usually through the episiotomy scar. This relieves the symptoms but is followed by a persistent opening which closes and reopens at intervals. Subsequent abscesses may also occur. How does this infection start? A satisfactory explanation is that while the episiotomy wound is being sutured, a suture is inadvertently passed too deeply. It pierces the rectal wall, goes through the mucosa and then passes back through the episiotomy wound, carrying the rectal flora with it. Thus the needle hole itself can be the future internal opening of the fistula in the rectum, and the external opening will either be one of the external needle openings or be present in the center of the episiotomy scar. This complication can be avoided by keeping a gloved finger in the rectum when placing the deep sutures or by doing a rectal palpation after placing the sutures. If the latter is done and a suture is palpated in the rectum, the suture should be cut in the episiotomy wound and withdrawn through the rectum. If the suture is drawn out through the wound itself it will contaminate the area by dragging the rectal portion into the open wound, thus inoculating it with pathogenic organisms.

Rectovaginal fistulas may develop after infection of the episiotomy wound. In this condition a tract extends between the rectum and the vaginal mucous membrane, in contrast to fistulae in ano, in which the tract extends from the rectum to the perianal skin.

TREATMENT

When tenderness and edema of the episiotomy scar are present and infection has started, hot applications are exceedingly helpful in the relief of pain and in the localization of the abscess. Often the wound ruptures of its own accord. Early incision through the scar will prevent burrowing of the pus and greater involvement. Occasionally there may be a low grade infection, and the wound may heal without the formation of a fistula.

In the performance of an incision and drainage for abscess, it would seem advisable to identify and treat the fistula at the same time. However, the tissues are usually edematous and the internal opening is usually sealed off, so that its identification is difficult and the procedure is not practical. After a few days, when the edema subsides and the pus is evacuated, the internal opening can be felt in the rectum just above the sphincter as a tiny hardened pea-sized area. To cure the fistula the internal and external openings should be connected by passing a soft probe gently through the external opening into the rectum and incising boldly down to the probe. This lays the tract wide open and allows it to heal over by granulation. It is not necessary to excise the tract itself. To prevent the incontinence due to complete division of the sphincter, a seton can be threaded around the sphincter and through the internal opening, then tied and left intact. At a later date, after some healing has occurred by granulation, the sphincter should be divided with the patient under local anesthesia, freeing the seton. This can be done in the office without greatly incapacitating the patient. Postoperatively, in addition to the routine of sitz baths, it is most important to see the patient frequently enough to do digital rectal dilatations in order to prevent too rapid bridging of the defect, which may result in the formation of closed-off areas which can subsequently abscess.

REPORT OF CASES

Case 1.—Mrs. H. R., a white woman aged 22, was first seen two months post partum. She was a primipara who had a thirty hour labor and an episiotomy. Three days post partum the patient began to have severe pain in the region of the rectum; this persisted for two weeks. An abscess formed in the peritoneum and was opened. The pain continued intermittently. At the time of examination the patient complained of pus and fecal drainage from the perineal region. Examination revealed two small pinpoint openings, which were about 1 cm. apart and just to the right of the episiotomy scar. An excision of the fistula in ano was performed. The two openings were connected, and then a probe was passed into the rectum and an incision was made to connect the internal and external openings. The patient had a normal convalescence, and the wound healed without discomfort.

Case 2.—Mrs. M. Y., a white woman aged 31, was seen six months post partum, having had a normal delivery and an episiotomy. The patient complained of some tenderness in the region of the episiotomy for several weeks. She had noticed some pus draining from the perineal region. Examination revealed a tiny furuncle-like area on the left side of the perineum. When this was opened a probe was easily passed along a sinus tract into the rectum. With the patient under local anesthesia, an incision was made down to the muscle and a seton was placed through the internal opening around the sphincter. Twenty days later the seton was removed with the patient under local anesthesia after the tract had been cut through. Recovery was uneventful.

[2] Kretzschmar, N. R., and Huber, C. P.: Study of 2,987 Consecutive Episiotomies, Am. J. Obst. & Gynec. 35: 621-626 (April) 1938.

CASE 3.—Mrs. C. W., a white woman aged 19, was seen five weeks post partum, having had a high forceps delivery and an episiotomy. The patient complained of severe pain in the rectum since the birth of her baby. Examination revealed that the perineal wound was entirely healed. There was no evidence of inflammation or tenderness. No fistula was present. On examination of the rectum two pea-sized areas were palpated on the left side in line with the episiotomy. The patient was high strung, and it was difficult to evaluate her complaint of rectal pain. The two tiny pea-sized areas in the rectum probably represented a place where a suture went through and healed by the formation of scar tissue but did not form an abscess with subsequent fistula. As the scar was well healed it did not seem justifiable to excise the scar or the indurated areas in the rectum. At present the patient does not complain strongly, but she still speaks of some discomfort in the region of the rectum.

CONCLUSION

Perianal abscesses with resultant fistulas do occur in a small number of cases following episiotomy. Such a sequela should be kept in mind.

EXCESSIVE SELF MEDICATION WITH NAPHAZOLINE HYDROCHLORIDE ("PRIVINE HYDROCHLORIDE")

PAUL S. MERTINS Jr., M.D.
Montgomery, Ala.

Rhinitis medicamentosa is a condition frequently associated with allergy or sinusitis. Recently, however, there have been an increasing number of unusually severe cases associated with nervous manifestations following excessive self medication with naphazoline hydrochloride ("privine hydrochloride" N. N. R.).

REPORT OF CASES

CASE 1.—A healthy man aged 28, who had been well until four months before, began using "solution privine hydrochloride 0.1 per cent" for a cold at the recommendation of a friend. His stuffiness became worse until he was using about 2 ounces (59 cc.) a week. He had lost 20 pounds (9.1 Kg.), was unable to sleep and was so nervous that he thought he was having a breakdown. Examination of the nose showed the turbinates to be grossly swollen; they were the dead gray color and the consistency of bubble gum. They could not be shrunk even by a mixture of cocaine hydrochloride and epinephrine ("adrenalin" N. N. R.). The sinuses were clear to transillumination, the sedimentation rate was normal and nasal smears did not suggest allergy. Results of physical examination and extensive laboratory examination were otherwise within normal limits. The patient was put on a regimen of sedatives, steam inhalations and ephedrine by mouth. After a stormy ten days he began to improve. One month later he reported that he was taking no medicaments and was gaining weight; his nervousness was gone. The nose looked normal.

CASE 2.—A child aged 3 years had increasing stuffiness of the nose following a cold six weeks before. During the previous week the mother had become alarmed by a nervous twitching and an impediment in speech. The mother stated that she was using "privine" full strength "by the gallon" (a prescription of her own) and that the child cried for it. There was no warning note on the bottle. All medicaments except a dilute solution of sodium chloride were discontinued. At the end of a week both the nose and the nervousness were improved.

CASE 3.—A young woman with mild chronic allergic rhinitis stated that she could not live without "privine" and used it every two hours. Her nasal tissues completely blocked the air passages and showed the dead gray color of rhinitis medicamentosa due to this drug. She was extremely nervous, had lost 8 pounds (3.6 Kg.) and for the past month had not been able to sleep without the use of sedatives. The blood pressure was 120 systolic and 80 diastolic. Medication with naphazoline hydrochloride was discontinued, but sedatives were given. Three days later the patient collapsed; the blood pressure was 85 systolic and 50 diastolic. At her insistence naphazoline hydrochloride was started again, and withdrawal of the drug is being attempted gradually.

COMMENT

These cases are not exceptional, but are characteristic of those which many rhinologists and allergists are seeing daily. Pharmacists report the impression that self medication with this agent is excessive and is increasing rapidly.

Differential diagnosis between sinusitis, allergic rhinitis or nasal psychoneurosis, with which it may be associated, is essential because the patient, as in most cases of rhinitis medicamentosa, will insist that the drug is his only help and will seldom recognize the true cause of his condition. Continuation or increase of his use of the medicament will eventually result in severer manifestations of disease.

Treatment consists in the withdrawal of the nasal medicament as rapidly as is consistent with the patient's health and will result in a cure comparable to the previous condition of the nose in from a week to three weeks. Sedatives, steam inhalations and mild protein silver ("argyrol") packs only ameliorate the severe discomfort of the first few days. I have found that other types of nose drops will not give relief and only seem to hinder the healing. Antihistaminic agents and sulfonamide compounds have usually been given to the patients previously by friends. These drugs are of no benefit except for complications. The administration of ephedrine by mouth often increases the nervousness of the patient.

The purpose of this report is not to condemn the ethical use of an excellent product but simply to warn that its uncontrolled abuse may result in serious disease, which can be diagnosed early if it is considered.

SUMMARY

1. Rhinitis from excessive self medication by naphazoline hydrochloride ("privine hydrochloride") is a rapidly increasing entity in allergic and nasal practice.

2. It produces a severe gray rhinitis of a most refractory nature with a severer form of nervousness than one would expect to result from nasal obstruction alone.

3. It is easily diagnosed by history and examination but must be distinguished from its complications.

4. Treatment, which consists in withdrawal of the medicament, will result in cure but is uncomfortable.

32 Clayton Street.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following report. HOWARD A. CARTER, *Secretary.*

GENERAL ELECTRIC INFRA-RED HEAT LAMPS ACCEPTABLE

Manufacturer: General Electric Company, Cleveland 12.

The General Electric Infra-Red Heat Lamps are self contained units and screw into any conventional socket. The conical bulb is coated with aluminum on the inside, making a reflector. The face of one model is made of lightly frosted glass and the other is red glass. The heat radiation from this lamp has therapeutic value, but the firm does not claim any special therapeutic benefit from the frosted or red glass faces (filters). The tungsten filament at the focus of the reflector draws 250 watts. The spectral intensity measurements presented by the company are characteristic of the radiation emitted by any incandescent tungsten. The Council has confirmed these data.

The generators, in the opinion of the Council, may be employed efficaciously whenever radiant heat is indicated. They may be prescribed by a physician for use in the home.

The Council on Physical Medicine voted to include the General Electric Infra-Red Heat Lamps in its list of accepted devices.

NEW CONCEPTS IN THE TREATMENT OF RELAPSING MALARIA

The prevention of relapses in malaria remains largely an unsolved problem despite the development of new and more potent antimalarial drugs. The probability of radical cure in an individual, or of cures in a group, Sapero[1] believes is determined by the factor of drug efficacy plus the factor of host immunity. The net effect of these is reduced or augmented by a third factor, the inherent characteristics of the species or strains of malaria concerned. Thus the attainment of radical cure either in an individual or the percentage of such cures in any group is not solely a matter of exact therapeutic method, as is commonly believed.

The variability of immune response is demonstrated by the fact that some persons who acquire malarial infection may experience complete cure without the benefit of drug therapy, while others fail to attain a radical cure despite the curative effects of both treatment and immune response. In this group fall the cases of relapsing malaria.

The four species of plasmodia which cause human malaria have distinctive qualities. Individual species of plasmodia and certain individual strains of a single species show inherent differences in their pattern of relapse in the human host and in their susceptibility to drugs. Plasmodium ovale, for example, is distinctive in that infections caused by it show little tendency to relapse and exhibit a high degree of drug susceptibility. Remarkably small doses of quinine usually suffice to bring about radical cure. Plasmodium vivax infections, in contrast to those caused by Plasmodium ovale, exhibit a strong tendency to relapse. The usual course in vivax infections is that shortly after recovery from the primary attack a series of relapses takes place. Then there follows a period of clinical latency. Usually this lasts from seven to eleven months, after which another series of relapses may occur. These distinctive qualities are exhibited not only by the species but also by certain individual strains of P. vivax, which also vary in their response to treatment. These characteristics of species and strains appear to be of a remarkably stable nature.

Most workers in this field, Sapero points out, explain the mechanism by which distinctive relapse patterns are exhibited by various species and strains of plasmodia by accepting a hypothetical principle which postulates the existence of an exoerythrocytic cycle in man. Thus relapses in malarial infections are said to be of two types: those which follow as a result of parasitic activity in the exoerythrocytic cycle and those which follow from renewed parasitic activity in the conventional erythrocytic cycle. A new version of parasitic activity in man is that, following inoculation, sporozoites enter fixed tissue cells, where the parasites are believed to undergo a distinct cycle of development, a so-called exoerythrocytic cycle; subsequently they are discharged into the blood stream and there begin the erythrocytic cycle. Persistence of infection and relapse are both closely linked with the exoerythrocytic development of parasites. Relapses are conceived to follow periodic discharges of tissue forms into the blood stream.

Chemotherapeutic agents in general use in malaria exhibit a highly selective action. Drugs capable of eradicating trophozoites of the erythrocytic cycle are incapable of a like action on preerythrocytic forms. Conversely, drugs potent against preerythrocytic parasites are largely without effect on erythrocytic forms. Quinine, quinacrine and chloroquine, as far as practical benefit against asexual forms is concerned, are active only on erythrocytic forms. Plasmochin and pentaquine act exclusively on exoerythrocytic forms. The newer approach demands that therapy be directed toward the prevention of the exoerythrocytic type of relapse as well as toward the erythrocytic type. Either a single drug must be discovered which has the dual capacity of acting against the parasites of both exoerythrocytic and erythrocytic phases, or a combination of two drugs which will accomplish the same result must be used. Paludrine appears unique, since it represents the first discovery of a drug which has appreciable dual activity against both erythrocytic and exoerythrocytic forms. Some success has been achieved by the simultaneous use of combining quinine with plasmoquine or pentaquine. This combination provides an attack on forms of both cycles.

Sapero concludes that the problem of preventing relapses depends much on the understanding of the possibility of an exoerythrocytic cycle in man and of the two types of reactivation: the exoerythrocytic relapse and the erythrocytic recrudescences. Radical cure of the infection involves the use of drugs capable of both exoerythrocytic and erythrocytic activity. Drug susceptibility and the pattern of relapse appear to be the essential elements peculiar to species or strains of species which are important in determining whether cure or clinical reactivity will follow.

INFLUENZA VACCINES

Less than thirty years ago more than 21,000,000 people throughout the world died of a pandemic disease the cause of which at that time was unknown. Human influenza virus was discovered by Smith, Andrewes and Laidlaw[1] in 1933. The possibility of a major epidemic during World War II led to experiments on producing, on a large scale, a vaccine which would protect our armed forces and civilians against influenza. The first vaccine prepared on a large scale contained inactivated influenza virus obtained by the elution of adsorbed virus from chick red cells.[2] This vaccine produced protection against influenza, but it contained about 80 per cent of impurities in the form of nonvirus protein materials. The second vaccine produced on a large scale was prepared by the selective removal of inactivated virus from the extraembryonic fluids of the infected chick embryo by high speed centrifugation.[3] This method yielded a vaccine containing few impurities and consisting almost wholly of purified inactivated virus. The centrifuge method was accepted by the U. S. Army in April 1945 as an alternative for the adsorption and elution method used during the preceding year. The Army was vaccinated against influenza in the fall of 1945, and where comparative results were obtained they indicated that influenza among the vaccinated was very much less prevalent than it was among the nonvaccinated.[4]

In the meantime two additional influenza vaccines have appeared on the market, one consisting of inactivated virus precipitated on calcium phosphate[5] and the other of inactivated virus precipitated on protamine.[6] Four different influenza vaccines are available therefore at present, all prepared from the extraembryonic fluids of infected chick embryos and containing both type A and type B influenza viruses inactivated with solution of formaldehyde. The fluids however are processed by different methods and yield vaccines which differ in their content of impurities or nonvirus materials. The centrifuge method, Stanley[3] found, yields the purest product, and in addition the yield and the possible concentration of virus are greater.

In a study of allergic reactions produced in children by the eluate-type influenza vaccine, Ratner and Untracht[7] found that the positive reactions were related in large measure to the egg protein in the vaccine. A few of the suggestive reactors were shown to be sensitive to the solution of formaldehyde and not to egg. It was suggested that vaccines produced from chick embryos should not be given to persons who are highly sensitive to egg protein. They recommended that all persons be tested intradermally with 0.02 cc. of undiluted vaccine before the administration of each prophylactic dose of vaccine. Although its occurrence is rare, profound or fatal anaphylaxis has resulted from the use of influenza vaccine in untested patients. With respect to potential allergic reactions the centrifuge-type vaccine has definite advantages over the other three types. The reactions produced by the centrifuge-type vaccine in a highly egg-sensitive person were found to be far less than those produced by the eluate-type of influenza vaccine.[8] It seems obvious therefore that the most highly purified vaccine, the centrifuge-type, should be used whenever possible. Its manufacture and sale to civilians are not restricted by patents.

Current Comment

FATIGUE AND SWEATING

The maintenance of efficiency under conditions of high temperature and humidity is dependent on the ability to maintain the rate of sweating. The factors which control the rate of perspiration have been studied by Gerking and Robinson,[1] who caused experimental subjects to do a constant amount of work on a treadmill under controlled conditions of temperature and humidity. If the initial rate of sweating was moderate, 600 to 800 Gm. per hour, it was maintained for a long period. If, however, the initial rate was about 1,400 Gm. per hour, the sweating rate declined from 10 to 80 per cent by the sixth hour of the experiment. The decline in sweating rate was greater in humid than in dry heat and also greater when men wore army tropical uniforms than when they wore only shorts. Water balance was maintained by ingestion of 0.1 per cent sodium chloride solution. The decline of the rate of sweating is probably due to some sort of fatigue of the sweating process. It results in failure of the cooling mechanism and a rise of body temperature of about 2 degrees centigrade.[2] The sodium chloride content of the sweat becomes greater (more like the plasma) as work is prolonged. Best performance is achieved by replacing hour by hour the water lost in the sweat. Replacement of salt or of glucose on an hour by hour basis is of little advantage compared with water replacement.[3]

CANCER OF THE LUNGS IN PULMONARY TUBERCULOSIS

Tuberculosis and cancer may occur in the lungs at the same time. The number of such cases appears to be increasing. Several cases in which simultaneous tuberculosis and cancer of the lungs were diagnosed during life have been analyzed by Gerstl, Warring and Howlett.[1] They state that the cancer may escape detection because tuberculosis alone can cause the prominent symptoms and signs. Any failure to conform to the pattern of uncomplicated tuberculosis should lead to prompt investigation. In their cases x-ray evidence of major bronchial obstruction or of a relatively circumscribed solid mass led to more precise diagnostic procedures, such as bronchoscopy, biopsy of suspected metastatic lesions, study of cell blocks of sputum and pleural sediment and puncture biopsy. None of the cases described were considered operable, but the complete diagnosis resulted in a more definite prognosis and in better management. The best treatment requires a correct and complete diagnosis as early as possible. "Since pulmonary resection is now feasible in many cases of tuberculosis, the practical desirability of much earlier diagnosis of coexisting cancer is apparent. It is, perhaps, not too much to hope that diagnosis of cancer in an operative stage may occasionally be accomplished in spite of the added difficulty which exists when tuberculosis is also present."[1] Cancer should be suspected regularly in pulmonary tuberculosis in the older age group. The differentiation between certain tuberculous and cancerous pulmonary lesions, whether concurrent in the same case or unmixed, requires special efforts. Siltzbach[2] points out that mass chest surveys with x-rays may reveal unsuspected silent cancer of the lung, especially in the upper lobes of persons over 40. He reports 2 such cases treated for tuberculosis seven and sixteen months before the correct diagnosis was made.

STATE OF VITAMIN A IN MILK

Both the food pigment carotene and vitamin A itself contribute to the vitamin A potency of milk fat. This potency is supplied to a considerable degree by carotene in the milk fat of the Jersey and Guernsey breeds,[1] whereas vitamin A itself is more important in this respect in the Holstein and Ayrshire breeds. A recent study[2] has described further the nature of the vitamin A in bovine milk and colostrum. This food factor, being an alcohol, can exist either free or esterified with a fatty acid. By chromatographic analysis it was shown that 98 per cent of the vitamin A in both colostrum and milk is in the esterified form in all of the breeds studied—Guernsey, Jersey, Holstein and Ayrshire. This is interesting in view of the fact that the major part of the vitamin A in the blood of the same cows was in the alcohol form. Whereas the chemical character of the vitamin A was identical in both colostrum and milk, the same study demonstrated that the yellow carotenoid pigment consisted more largely of carotene in colostrum (95 per cent) than in milk (89 per cent).

THE MOTIVATIONS OF CUSTER'S LAST STAND

The ship *Swanton* arrived in New Orleans on Dec. 11, 1848 with some 280 steerage passengers, 16 of whom died of cholera during the passage. The packet boats plying the Mississippi River spread the infection with great rapidity to Memphis, St. Louis, Nashville, Wheeling and Pittsburgh. The epidemic subsided during the winter, to flare up in the spring in true epidemic form. This was the sequence for almost three decades. In 1867 cholera broke out at Fort Riley. George Armstrong Custer, at that time a young officer with a brilliant record, a major general at the age of 27, a lieutenant colonel in charge of a cavalry regiment on completion of the Union War, left his field of duty and returned to Fort Riley, having turned over the command of the regiment to the next senior officer. This was done without permission, because the young officer feared for the safety of Mrs. Custer, who then lived at Fort Riley. For this violation of the Articles of War, charges were preferred and court martial procedure was instituted. One year later Custer was charged with abandoning Major Elliott and his detachment while the latter was making a flanking attack under orders. The court martial convicted Custer and sentenced him to loss of rank and pay for one year. On the completion of his sentence Custer rejoined his regiment no longer the favorite of his superiors, no longer the "boy general." He was, in fact, a humiliated man, a victim of persecution, nurturing rancor in his heart and a desire to reestablish himself despite his petty persecutors. Dr. Paul R. Hawley[1] believes this desire to reestablish himself as a great military hero led to the final erratic conduct which culminated in the utter defeat by the Indians of Custer and his command and his own destruction. Menninger[2] says that Custer was psychopathologic, characterized by excessive vanity and disregard for the feelings or safety of others, a lack of loyalty either to cause or to friends, disregard of the principles of humanity or the established code of ethics, and at times a conspicuousness of achievement passing for success under circumstances in which ruthlessness and boldness are to some advantage. Menninger further points out that when such types were encountered among the enlisted men in World War II they were unceremoniously "boarded out on section VIII," which meant that they were dismissed from service because of inaptitude. In the case of officers of high rank this procedure could not be applied with the same ease and dispatch. This explains certain disastrous results, as far as the morale and even the lives of the men in charge of an incompetent leader are concerned.

ORGANIZATION SECTION

Council on Medical Service

HEALTH CENTERS UNDER THE HOSPITAL CONSTRUCTION ACT

Prepared for the Council on Medical Service by Dr. Dean F. Smiley,
Consultant in Health and Physical Fitness, Bureau of Health
Education, American Medical Association
Chicago

The first health center in the United States was established in 1912 in Philadelphia as a child health center. Since 1912 health centers of various types have been rapidly developed, and it is estimated there are now at least 150 in operation.

As one would expect from the title, most health centers have been primarily concerned with health promotion. Other functions have, however, been combined with health promotion to produce not only public health centers but also health and welfare centers, health and recreation centers, hospital health centers and public health and medical service centers.

PUBLIC HEALTH CENTERS

Typical of the public health centers are the district health centers, district substations, child health stations, health centers with borough offices, health and teaching centers of New York, Boston, Baltimore and other large cities and the county public health centers of Missouri, Tennessee, Alabama and other states.

In these public health centers, facilities are provided for all or part of the following activities: communicable disease control and immunization services, sanitation services, maternal, infant and child hygiene services, public health laboratory service, vital statistics and health education.[1] Particularly stressed are the preventive medical services (examining and advising) and the health educational services.

In localities where the medical care of the indigent and medically indigent are an administrative responsibility of the public health department, ambulatory clinic facilities are sometimes provided as in Topeka, Kan.,[2] and certain counties in Missouri, as a part of the public health center. Even if this is the case, the functions of the health center are still primarily preventive rather than curative. In Topeka, Kan., the staff for the health center clinic is provided by the local medical society operating under a voluntary, prepaid medical care insurance scheme by which Shawnee County prepays the medical care of its indigent and medically indigent families at a flat rate of $4 a month per family.

HEALTH AND WELFARE CENTERS

About 1935 Los Angeles experimented with the idea of combining health and welfare functions in its health centers.[3] Under the leadership of Dr. John Pomeroy, Los Angeles County attempted to provide diagnosis and treatment of indigent outpatients in its health centers, the practicing physicians of the county donating their services in these centers. The welfare functions were however eventually abandoned, and these centers are now operating as public health centers.[4]

Examples of health and welfare centers operated by private agencies are found in the eight health centers operated in Monmouth County, N. J., by the Monmouth County Organization for Social Service, Incorporated. In the thirty-five years since its inception in 1911, this organization has grown until it now employs thirty-one public health nurses and supervisors and includes eight rural health centers, six lay auxiliaries and a social service exchange carrying nearly 60,000 case histories.[5]

Since welfare agencies serve only a limited clientele, while public health agencies are concerned with the health of all citizens, it is obvious that close association with welfare agencies would be apt to limit rather than enhance and expand the activities of the public health agencies.

HEALTH AND RECREATION CENTERS

In 1938 Dr. Frank K. Safford Jr. submitted three models which he had developed over the preceding four years. All were for health centers for preventive medicine, recreation and education;[6] the first for a large slum clearance housing project, the second for an American city of 100,000 population, the third for a city of 35,000 population.

The plan, in the words of the designer, would be as follows: "The recreation is designed to attract people to join the center as members, paying a yearly membership fee. Then membership privileges would include free use of athletic facilities, the service of the diagnostic clinic and reduced rates in the eating places, theater, medical baths and educational facilities. In the diagnostic clinic, members of the center would receive physical examination, including routine x-rays, urine and blood tests, periodic consultations, instruction in preventive medicine, including advice about exercise, recreation and diet. The medical work would be carried on by a visiting staff of physicians who would devote so many hours weekly in the center clinic just as they do in other hospital clinics, with the difference that in the center (supported by recreation and membership) they would be paid for their services. . . ."

As far as is known, none of these projected centers have as yet been built in the United States, though the Pioneer Health Center of this type in Peckham, London, has been in operation for years.

HOSPITAL HEALTH CENTERS

For the past ten years the W. K. Kellogg Foundation at Battle Creek, Mich., has been interested in developing hospitals in seven of Michigan's rural counties as rural hospital-health centers.[7] The units are primarily efficient rural hospitals, but they have been given the title of health center because they provide, in addition to hospital services, home maternity nursing service, complete home laboratory service and, in one center, home x-ray service. The laboratory and x-ray facilities of each hospital are made available at low cost to the practicing physicians of the surrounding area. Though public health offices have not yet been established in any of these hospitals, such a combination is contemplated, and in one of the experimental counties the county health officer is at the same time superintendent of the county hospital, the Branch County Community Health Center.[8]

A short description of the hospital health centers was published in 1940.[1b]

PUBLIC HEALTH AND MEDICAL SERVICE CENTERS

In 1946 there appeared at least three recommendations for the construction in rural communities too small to support a 50 bed general hospital of health centers to include a limited number of beds for medical, surgical and maternity cases. The first of these recommendations[9] called for 5,500 to 6,000 square feet of floor space for the 10 bed hospital features, 2,000 square feet for the public health activities and 300 square feet for each private physician's and dentist's offices and examining rooms.

[6] Safford, F. K., Jr.: Health Centers for Preventive Medicine, Recreation and Education: Design Trends, Architectural Record, February 1938.

[7] There are ten of these hospitals in seven rural counties of Michigan as follows: Sheldon Memorial Hospital, Albion, Calhoun County; Allegan Health Center, Allegan, Allegan County; Haynes-Green County Memorial Hospital, Charlotte, Eaton County; Calhoun County Public Hospital, Battle Creek, Calhoun County; Community Health Center, Coldwater, Branch County; Pennock Hospital, Hastings, Barry County; Hillsdale Community Health Center, Hillsdale, Hillsdale County; Oaklawn Hospital, Marshall, Calhoun County; William Crispe Hospital, Plainwell, Allegan County; City Hospital, South Haven, Van Buren County.

[8] Information gained in personal conference with Mr. Graham Davis, director, Division of Hospitals, W. K. Kellogg Foundation, Battle Creek, Mich., Feb. 22, 1947.

The second[10] and third[11] recommendations in almost identical words called for public health and medical service centers "in outpost areas at present without hospital facilities." The six functions of these centers would be:

1. To serve as the local point about which public and voluntary agencies can coordinate their efforts to conduct a program of health education.

2. To serve as the headquarters for the official public health agency with offices for health officer, sanitarian and public health nurses. To "be the base for programs in sanitation and preventive medicine, such as immunization against preventable diseases, the early diagnosis of tuberculosis, control and treatment of venereal diseases, and maternal and infant care activities."

3. To make provision for the conduct of routine laboratory tests and x ray services. "It is contemplated that the physician himself or a nurse trained in the technics of the more commonly used diagnostic tests and examinations would operate these facilities In some instances, trained technicians could be employed"

4. Provisions of office facilities for the physician or physicians who are residents in the community.

5. "The provision of a few beds and proper sterilization and delivery room facilities in the public health and medical service center for the care of normal obstetric cases would be highly desirable."

6 "Some effort should be made to provide temporary facilities for treating emergency cases until suitable arrangements can be completed for transfer of the patient to a general hospital with a thoroughly competent professional service. A definite working arrangement should be formulated for affiliation between public health and medical service centers and a conveniently located general hospital."

HEALTH CENTERS DEFINED BY GOVERNMENTAL AGENCIES

The Hospital Survey and Construction Act of 1946[12] in section 631f states that "the term 'public health center' means a publicly owned facility for the provision of public health services including related facilities such as laboratories, clinics and administrative offices operated in connection with public health centers; . . ."

The Federal Register Document 47-1247;[13] filed Feb 11, 1947, provides the following definitions as a part of the Public Health Service Regulations issued pursuant to the provisions of section 622 of the Public Health Service Act as amended by the Hospital Survey and Construction Act of 1946 (Public Law 725, 79th Congress):

Section 10 1 (p) *Public health center* A publicly owned facility utilized by a local health unit for the provision of public health services, including related facilities such as laboratories, clinics and administrative offices operated in connection with public health centers.

Section 10.1 (q) *Local health unit* A single county, city, county city or local district health unit, as well as a state health district unit where the primary function of the state district unit is the direct provision of public health services to the population under its jurisdiction

Section 10 1 (r) *Public health services.* Services provided through organized community effort in the endeavor to prevent disease, prolong life and maintain a high degree of physical and mental efficiency. In addition to the services which the community already provides as a matter of practice, the term shall include such additional services as the community from time to time may deem it desirable to provide

TYPES OF HEALTH CENTERS TO BE CONSIDERED

Type 1 would offer five public health services only. It would be very simple and not house any full time staff. The facilities would be in use only when public health workers from the county unit were present or public health clinics were being conducted by local physicians temporarily employed by the health department.

Type 2 would offer the five public health services and in addition limited public health laboratory services and limited clinical laboratory services. The full time services of a medical technologist would probably be required. Reports of tests would be submitted to the patient's physician not to the patient.

Type 3 would offer the five public health services and the three diagnostic services, i. e. public health laboratory, clinical laboratory and x-ray laboratory services.[10] It would require the full time services of a medical technologist trained also as an x-ray technician. Films and reports would be sent to the patient's physician, not to the patient.

Type 4 besides the five public health services and three diagnostic services would provide the practicing physicians of the community the use of office space close to the diagnostic facilities.

Type 5 would add emergency medical service and maternity service. This would require twenty-four hour service, 1 to 4 beds, kitchen and possibly laundry service.

Type 6 would add a 10 bed hospital with 5,500 or 6,000 square feet of floor space devoted to beds and adjunct services. Probably a minimum of 10 to 15 full time employees would be required for the hospital facilities alone.[9]

Type 7 would add offices for social and welfare workers and *possibly clinic facilities for the medical and surgical care of the indigent.*

Type 8 would add recreational facilities suited to the locality.[6]

COMMENTS

The most important needs to be met by the Hospital Survey and Construction Act in the order of their urgency would appear to be: (*a*) Community hospitals of 50 beds or more for rural communities of 20,000 or more. (*b*) Community clinics[14] of 10 or more beds for rural communities of 4,000 to 18,000. (*c*) *Public health centers to serve as headquarters for single county or multicounty public health units.* (*d*) *Public health* centers to serve as extensions of the single county or multicounty public health units into the smaller communities

The need for public health centers to serve as extensions of the single county or multicounty public health units into communities of 4,000 to 18,000 is real but in my opinion not urgent. Acceptable space for this activity can frequently be rented and maintained at a cost much less than would be the case if a new building was erected.

The really difficult problem is undoubtedly establishing and *operating the community clinics for the communities of less than 20,000.* Hospital administration authorities are in apparent agreement as to the inefficiency of setting up full fledged hospital facilities with kitchen, laundries and laboratory, x-ray and physical medicine facilities for less than 50 beds. Difficult as it is, this problem would appear to offer better hope of effective attack if the primary objective of providing beds for the care of the sick in rural communities more than 30 miles from a general hospital is recognized and met head on The plan of establishing such facilities under the title of public health and medical service centers is of doubtful wisdom for two reasons; *first it confuses the issues, mixing the difficult and urgent problem of providing sick beds with the relatively simple and* nonurgent problem of providing physical facilities for public health nurses and other workers; second, it complicates administration by mixing preventive medical activities which are under the administration of the local public health department with hospital and treatment activities neither of which is under the administration of the local public health department.

If recently trained physicians are to be attracted to such rural communities to begin their practice, there must be made available in the community not only clinical laboratory and *x-ray service but twenty-four hour bedside nursing service* as well. *To obtain this latter service some type of cottage hospital* or community clinic would appear to be essential

[12] Public Law 725, 79th Congress, chapter 958, 2d session, S. 191: An act to amend the Public Health Service Act to authorize grants to the states for surveying their hospitals and public health centers and for planning construction of additional facilities, and to authorize grants to assist in such construction [illegible] 1946. State Agencies Designated to Administer [illegible] ral Security Agency, U S. Public Health Servi [illegible] Facilities, Washington, D C, Dec. 27, 1946.

[13] Reprint from Federal Register, Division of Hospital Facilities, Title 42, Public Health, chapter 1, Public Health Service, Federal Security Agency (F. R. Doc *47-1247; filed Feb. 11, 1947, 8:54 a m*).

[14] It is suggested that small community hospitals of 10 to 40 beds offering a limited medical and maternity service but not including major surgery or specialty services, be given the term "community clinic." Plans and equipment for such units have been proposed in the following publications Hospitals—Architectural Record's Building Types Study, Number 104, Architectural Record, August 1945 Equipment for a 10 Bed Hospital and Health Center, 41546, Federal Security Agency, U. S Public Health Service Hospital Facilities Section Kinde, M. R: Diagnostic Facilities in Rural Areas, Hospitals, January 1943 Sarvis, L J, and Davis, G. L: South Haven Hospital. It Is Efficient and Expandable, *Hospitals,* September 1943

I have no panacea to offer for this problem. I simply point out (*a*) that combining public health center activities with beds does not simplify in any way the problem of maintaining those beds in a small community, (*b*) 60 per cent occupancy of such rural beds would probably have to be considered reasonable utilization (there may be thirteen classifications of patients in a 30 bed hospital). (*c*) While McGibony[14] estimates the cost per patient at $9.40 a day in such a 10 bed hospital, Beelman and Steinmeyer[15] reported in 1945 that fifty-two Kansas hospitals averaging 12 beds each showed costs of only $4 99 a day per patient with an occupancy of 50 per cent. This problem is primarily a hospital administration problem, i. e. how to extend hospital facilities to communities of less than 20,000; the public health problem of extending public health services from the county or multicounty center to the smaller communities is only a minor and incidental part of this big problem.

Public health centers should limit their activities to the generally accepted public health program, adding on functions as the community by organized action places additional responsibilities (such for example as administering the provisions of ambulant medical care to the community's indigent population) on the health department.

Whether in base hospital service areas, intermediate hospital service areas or rural hospital service areas every effort should be made to place the public health headquarters as close as is practicable to the hospital (and the medical school if there is one).[16] Thus there will be developed eventually base medical centers, district medical centers and community medical centers, with the public health centers as one unit of the larger medical center.

In the base and intermediate hospital service areas the public health center had probably best be in a separate building close to the hospital (and medical school if there is one). In rural hospital service areas the public health center may well occupy space in the community hospital or in the community clinic, but the two projects should be kept administratively independent of each other.[16] All of these would be type 1 public health centers.

If a public health center is required in a rural community which does not have and does not need a community hospital or a community clinic, it is suggested that consideration be given to providing in such a center not only facilities for communicable disease control efforts, sanitation activities, maternal-infant-child hygiene measures, vital statistics, health education and public health laboratory service but also facilities for clinical laboratory service and limited x-ray service (type 2 or type 3 centers). If the local practitioners in the area desire office space in such a center in order to obtain easier access to the laboratory and x-ray facilities there should be no serious objection to that request, and a type 4 center should be established

If means are developed for establishing community hospitals and community clinics where needed there would appear to be no need for public health centers of types 5 and 6

In my judgment the advantages of combining welfare facilities or recreation facilities in the public health center would not be sufficient to outweigh the costs and administrative confusion resulting from such a combination, and I see no place for centers of types 7 and 8 under the terms of the Hospital Survey and Construction Act of 1946

CONCLUSIONS

1. At least fourteen different functions have been assigned the health center since 1912.

2. Of these fourteen functions it is recommended that only five (communicable disease control efforts, sanitation, maternal-infant-child hygiene measures, vital statistics and health education) be generally included under the title of public health center as that title is used in the Hospital Survey and Construction Act of 1946.

3. It is recommended that public health centers be established as needed[17] and as close as is practicable to hospitals and medical schools (if any) in base hospital service areas, intermediate hospital service areas and rural hospital service areas and that they be integral parts of base medical centers, district medical centers and community medical centers. It is, however, recommended that at every level the public health center be kept administratively independent and that the differing needs of hospitals and public health centers for quiet and for accessibility be kept in mind.

4. Public health centers to serve as headquarters for county and multicounty public health units are much more urgently needed than are rural public health centers serving as extensions of county and multicounty public health units.

5. It is recommended that in rural communities of 4,000 to 18,000 in need of sick beds but not large enough to afford a 50 bed general hospital "community clinics" of 10 to 40 beds be provided by hospital authorities rather than "public health and medical service centers" provided by public health authorities. However, administratively independent public health centers may sometimes be advantageously housed in the community hospital or community clinic. Such community clinics should be so organized and administered that they will not infringe on the private practice of medicine by physicians.

6. In those rural communities where bed service is available from neighboring community hospitals and the urgent need is for facilities for public health and diagnostic facilities it is recommended that the public health center shall provide facilities not only for the traditional six point public health service but also for clinical laboratory service and limited x-ray service. Offices for the part time use of the practicing physicians of the community should also be included if the physicians so desire.

7. In the interests of economy and administrative efficiency it would appear generally wise to avoid combining medical service functions, hospitalization functions, welfare and social service functions or recreational functions with public health functions in the public health centers projected under the terms of the Hospital Survey and Construction Act of 1946 The public health center should, however, include facilities for meeting effectively any responsibility laid on the public health department by the local community.

Woman's Auxiliary

OFFICERS OF WOMAN'S AUXILIARY TO THE AMERICAN MEDICAL ASSOCIATION

Following are the national officers, directors and chairmen of standing committees for 1947-1948 of the Woman's Auxiliary to the American Medical Association:

President—Mrs Eustace A. Allen, 18 Collier Rd N W., Atlanta, Ga.
President Elect—Mrs Luther H. Kice, 95 Brook St., Garden City, Long Island, N. Y.
Treasurer—Mrs A. A Herold, 1166 Louisiana Ave, Shreveport, La.
Vice Presidents:
  First—Mrs David B. Allman, 104 St Charles Place, Atlantic City, N. Y.
  Second—Mrs. Leo J. Schaefer, 700 Highland, Salina, Kan
  Third—Mrs E Arthur Underwood, 3725 Wuana Vista Drive, Vancouver, Wash
  Fourth—Mrs W. W. Potter, 129 Kenesaw Terrace, Knoxville, Tenn
Constitutional Sec—Mrs George Turner, 3006 Silver Street, El Paso, Texas
Directors:
  One year—Mrs Jesse D Hamer, 1819 N. 11th Ave., Phoenix, Ariz; Mrs James P. Simonds, 234 E Pearson St, Chicago 11, Mrs J. L Stevens, 67 N. Mulberry Rd, Mansfield, Ohio; Mrs. Ralph Eusden, 4360 Myrtle Ave, Long Beach 7, Calif
  Two years—Mrs I J. Bridenstine, Terry, Mont; Mrs. U. G McClure, 1592 Quarrier St, Charleston 1, W. Va.; Mrs. David S. Long, Harrisonville, Mo
Chairmen of Stan [illegible] ittees.
  [illegible] Simonds, 234 E Pearson St, Chicago 11.
  [illegible] plewhite, 240 Bushnell St, San Antonio, Texas.
  [illegible] dison, 1100 N LaSalle St, Chicago 10
  [illegible] chaefer, 110 E Whitman St, Toccoa, Ga.
  [illegible] B Allman, 104 St Charles Pl, Atlantic City, N. J.
  Postwar—Mrs Rollo K Packard, 4940 S East End Ave, Chicago 15.
  Program—Mrs Ralph Eusden, 4360 Myrtle Ave., Long Beach 7, Calif.
  Public Relations—Mrs. Harold F. Wahlquist, 129 W. 48th St, Minneapolis
  Revisions—Mrs Roscoe E. Mosiman, 2686 Magnolia Ave, Seattle.
  Parliamentarian—Mrs. Clarence G Goodwin, 4646 S. Woodlawn Ave, Chicago 15
  Historian—Mrs Jesse D. Hamer, 1819 N. 11th Ave, Phoenix, Ariz.

---

[15] Beelman and Steinmeyer. Kansas Government Journal, July 1945.

[16] Dr Haven Emerson has pointed out that while hospitals are best built where there is freedom from traffic noise, public health centers are most effective when most easily accessible to the public This point is important and should not be ignored in the effort to centralize health and medical facilities

[17] The Hospital Survey and Construction Act of 1946 definitely limits the number of such centers in thickly populated states to one per 30,000 people; in states having a population of less than 12 persons per square mile to one per 20,000 people

Official Notes

STEPHEN GRAHAM CHANGES TIME

The A. M. A.-Mutual radio program Stephen Graham—Family Doctor will change time with its extension from July 28 to November 17.

Beginning July 27 the program will be heard at 2 p. m., Eastern daylight time, including the New York outlet WOR not heretofore available. In the Middle West the program will be on the air at 1 p. m. Central daylight time; in the Mountain areas at 12 noon, Mountain daylight time, and on the Pacific Coast 11 a. m., Pacific daylight time.

There are numerous advantages to this time change. There is a larger listening audience at 2 p. m. than at 10:30 p. m. in the populous Eastern areas. The Hooper Rating Organization will now be able to estimate our audience, whereas no Hooper ratings are taken after 10:30 p. m. Sunday is a fine radio listening day for millions of people who have leisure not available to them on other days.

A specific request is hereby made to county medical society *officers in communities where Stephen Graham is broadcast. It* is requested that they communicate with the radio station program director, asking him what telephone calls and other communications were received on the disappearance of Stephen Graham from the customary Monday evening time spot. Details of such happenings should be reported to the Bureau of Health Education, American Medical Association, Chicago 10. Such information is of great value to the Bureau and to the radio network.

Washington Letter

(From a Special Correspondent)

July 30, 1947.

Liquidate Maternity and Infant Care Program

The Emergency Maternity and Infant Care program is being closed off books of the United States Children's Bureau under the liquidation program ordered by Congress starting July 1 in appropriations for the new fiscal year. Care will be provided for all wives and infants now receiving care as well as those who were eligible as of June 30. A total of more than $124,900,000 has been allotted to the states to cover the cost of the program. Congress has appropriated another three million dollars for the two fiscal years 1947-1948 and 1948-1949 to cover liquidation costs. All of 1,421,000 cases were approved for care. International experts in child medical care and nutrition from twelve countries met here to give technical advice to the International Children's Emergency Fund of United Nations. The fund comprises assets made available by UNRRA and contributions by governments, to which Congress has authorized another 40 million dollars.

Dean's Committee Endorses Bradley's Policies

General Omar Bradley's handling of the Veterans Administration was endorsed by the Dean's Committee of Baltimore in its report on organization of professional staffs of the Veterans Administration Fort Howard and Perry Point hospitals. The chairman is Dr. H. Boyd Wylie, acting dean, University of Maryland Medical School, and members are Dr. Alan M. Chesney, dean, Johns Hopkins Medical School of Medicine and College of Physicians and Surgeons; Dr. Lewis P. Gundry and Dr. Harry C. Hull, Maryland University, and Dr. Alan C. Woods and Dr. Perrin H. Long, Johns Hopkins. The report said that "few of the members of the staffs of the University of Maryland or Johns Hopkins hospitals would be participating in the program were it not for the policies established by General Bradley." The report said that doctors enlisted for service because "it permits them to maintain a high type of medical care and treatment of veterans; it is relatively free from the stifling effects of 'red tape' and bureaucracy; it permits the doctors to practice under conditions comparable to those existing in the best civilian hospitals in Baltimore; it is free (or has been so far) from so-called politics."

Atomic Energy for Health Purposes

The Atomic Energy Commission has reported that it is trying to turn atomic energy into peacetime uses, particularly in the field of health and eventually for the use of atomic energy for power. A statement outlining development of atomic weapons added "An important beginning has been made at exploiting peacetime uses of atomic energy. Radioisotopes, a most promising research tool in chemistry, biology and medicine, and of great promise in agriculture and metallurgy, are being produced and distributed in ever increasing quantity. Shipments of radioisotopes to hospitals and other research institutions now exceed 100 per month. Heavy hydrogen, another isotope of particularly great use in many kinds of research, is available for the first time at low cost."

Higher Pay for Service Doctors

Representative Blackney, Michigan Republican, has submitted to Congress a bill to raise pay of armed forces and U. S. Public Health Service doctors. A medical officer's base salary would be increased $100 a month and specialists an additional 25 per cent. Mr. Blackney estimates costs of the legislation around $9,000,000 a year. The proposal was advanced to meet an "alarming" shortage of service doctors. The income of the average civilian doctor is more than double that of medical officers. Mr. Blackney cited testimony of General Eisenhower, Army chief of staff, that the present Army Medical Corps is sufficient to maintain an army of only 200,000 men, while the strength of the Army is now a million men. Navy medical needs are similarly acute.

Advocates Pelvic Examination for Wacs

Senator Byrd of Virginia has offered an amendment to pending legislation to incorporate the Woman's Army Corps into the Regular Army which would require pelvic examinations of Wacs by doctors, preferably women doctors and specialists in the field. The Army Medical Corps is reported to take the stand that annual or semiannual pelvic examination of women in the Army is unnecessary because out of 115,767 women in the Army during the second world war there were only 187 cancers, 55 involving the pelvic organs. It is contended that a pelvic cancer incidence of 55 per 115,000 might be reduced by more expert examination and early detection of cancer symptoms in young women entering the service.

Coming Medical Meetings

American Association of Medical Record Librarians, New York, Hotel Commodore, Sept. 7-12. Mrs. Adaline Hayden, 18 E. Division St., Chicago, Executive Secretary.

American Association of Obstetricians, Gynecologists and Abdominal Surgeons, Hot Springs, Va., The Homestead, Sept. 4-6. Dr. James R. Bloss, 418 Eleventh St., Huntington 1, W. Va., Secretary.

American College of Surgeons, New York, Waldorf-Astoria Hotel, Sept. 8-12. Dr. Paul B. Magnuson, 40 E. Erie St., Chicago 11, Secretary.

American Congress of Physical Medicine, Minneapolis, Hotel Radisson, Sept. 2-6. Dr. Richard Kovacs, 2 E. 88th St., New York 28, Secretary.

American Congress on Obstetrics and Gynecology, St. Louis, Municipal Auditorium, Sept. 8-12. Mr. Karl S. Richardson, 24 West Ohio St., Chicago, Business Manager.

American Roentgen Ray Society, Atlantic City, Sept. 16-19. Dr. H. Dabney Kerr, University Hospitals, Iowa City, Secretary.

Colorado State Medical Society, Denver, Shirley-Savoy Hotel, Sept. 17-20. Mr. Harvey T. Sethman, 1612 Tremont Place, Denver 2, Executive Secretary.

Michigan State Medical Society, Grand Rapids, Pantlind Hotel, Sept. 24-26. Dr. L. Fernald Foster, 2020 Olds Tower, Lansing 8, Secretary.

National Medical Association, Los Angeles, Aug. 18-22. Dr. John T. Givens, 1108 Church Street, Norfolk 10, Va., Secretary.

Nevada State Medical Association, Reno, Sept. 4-6. Dr. Moreton J. Thorpe, 17 N. Virginia St., Reno, Secretary.

Oregon State Medical Society, Portland, Sept. 4-6. Dr. Thomas S. Saunders, 1020 S. W. Taylor St., Portland 5, Secretary.

Pennsylvania, Medical Society of the State of, Pittsburgh, Hotel William Penn, Sept. 15-18. Dr. Walter F. Donaldson, 500 Penn Avenue, Pittsburgh 22, Secretary.

Southeastern Dermatological Association, Knoxville, Tenn., Hotel Andrew Johnson, Aug. 31. Dr. A. H. Lancaster, 608 W. Main Ave., Knoxville, Secretary.

Utah State Medical Association, Salt Lake City, Sept. 11-13. Dr. Ray T. Woolsey, 610 McIntyre Bldg., Salt Lake City 1, Secretary.

Western New York and Ontario Urological Society, Saranac, N. Y., Saranac Inn, Sept. 3-6. Dr. Albert M. Crance, 525 S. Main St., Geneva, N. Y., Secretary.

GOVERNMENT SERVICES

ARMY

SEEK FUNDS FOR BUST OF WALTER REED

The American Society of Tropical Medicine will sponsor the campaign to raise funds to provide a bust of the late Major Walter Reed of yellow fever fame to be placed in the Hall of Fame at New York University (The Journal, July 5, p. 909). The Surgeon General's Office will aid in the campaign. It is planned to collect the funds and have the sculpture completed so that it may be dedicated at the time of the International Congress for Tropical Medicine and Malaria, which will be held in Washington, D. C., next spring Contributions are requested and should be sent to the secretary-treasurer, American Society of Tropical Medicine, National Institute of Health, Bethesda 14, Md. Walter Reed is the first member of the medical profession to be chosen for a place in the Hall of Fame for Great Americans on the campus of New York University. He is the seventy-seventh historical figure chosen for this honor.

MICROFILM COPIES OF MEDICAL LITERATURE

The Army Medical Library, Washington, D. C., has a collection of more than a million volumes that have been gathered, catalogued and indexed since 1836, a treasure of medical literature which goes back in some cases to medieval times. Physicians, libraries and professional workers may obtain facsimile replicas of this material on 35 millimeter film through the microfilm service of the library. Those requesting the material receive the film reproduction reduced to the size of a large postage stamp for each page, which can be read in small size film viewers which enlarge the microfilm or they can be projected to readable size in special machines available in many libraries. During 1946 more than six million pages of medical literature were distributed by the Army Medical Library on microfilm. Articles in medical periodicals are duplicated on microfilm for 50 cents each, and books for 50 cents for each fifty pages or fraction thereof.

LOW POSTWAR VENEREAL DISEASE RATE

The War Department has announced that the army venereal disease rate at home and abroad has reached a postwar low. Present incidence in Europe is 23 per cent below the July 1946 high, in the Pacific 50 per cent below the October 1946 high, and in the United States 47 per cent below the April 1946 high. The sharp drop is considered by the Army to have been brought about by the stringent regulations outlined by Secretary of War Patterson last January.

HOSPITAL AT MINOT, NORTH DAKOTA

The contract for the Veterans Administration hospital at Minot, which has been let by the Army Corps of Engineers, calls for a cost of $3,395,000 without the laundry and nurses' quarters and the elevators. Work on the hospital will start at once.

PERSONAL

Col. Roary A. Murchison, M. C., U. S. Army, executive officer at the U. S. Army Percy Jones Hospital, Battle Creek, Mich., has been ordered to duty in Hawaii. Colonel Murchison served in England and France during World War II.

ARMY AWARDS AND COMMENDATIONS

Colonel Myron P. Rudolph

The United States of America Typhus Commission Medal has been awarded to Col. Myron P. Rudolph, M. C., U. S. Army, the citation reading in part as follows: He distinguished himself by exceptionally meritorious service by assisting the work of the United States of America Typhus Commission in Germany during the period March 15 to June 1, 1945, by planning and supervising with conspicuous success the administration and carrying out of details for the control of a full blown typhus fever epidemic raging in the midst of thousands of concentration camp internees. He rendered invaluable service by organizing in the Dachau camps and in southern Bavaria medical units and agencies to bring the typhus epidemic under control. His outstanding contributions to this effort are deserving of the highest praise. Dr. Rudolph graduated from Hahnemann Medical College in 1915 and entered the military service Oct. 5, 1917.

Major David Sloane

The Army Commendation Ribbon has been awarded to Major David Sloane, M. C., A. U. S., now of Dayton, Ohio. The citation read in part as follows: Your service with the Medical Department has been exceptional when compared with others of the same grade or similar position, and I wish to commend you for your outstanding contribution as chief of the orthopedic section, Thomas M. England General Hospital, Atlantic City, N. J., from Feb. 3, 1946 to May 10, 1946. Dr. Sloane graduated from Columbia University College of Physicians and Surgeons, New York, in 1925 and entered the military service in August 1942.

Captain Jerome D. Solomon

The Legion of Merit has been awarded posthumously to Capt. Jerome D. Solomon, M. C., A. U. S., of Chicago. The citation read as follows: For exceptionally meritorious conduct in the performance of outstanding services at Sansapor, Dutch New Guinea, from Aug. 18 to Sept. 4, 1944. Captain Solomon, though convalescing from a serious illness, volunteered to accompany his unit when it was ordered to an operational area known to be infested with typhus. Immediately on arriving, his organization was ordered to construct a field hospital for typhus cases and began to receive patients at once. Despite his weakened condition he insisted on aiding in the construction of the hospital and subsequently took charge of the first ward of patients. Short of personnel, and by this time suffering from the fever himself, he entered on his duties as a medical officer, caring for the sick night and day. Finally his lowered resistance, brought about by his prolonged activity, forced him to become a patient. He later died of typhus fever. By his great devotion to duty in caring for his comrades at a time when the medical facilities were taxed to their utmost, and with the knowledge that he was endangering his own life, Captain Solomon performed outstanding service beyond the call of duty. Dr. Solomon graduated from the University of Illinois College of Medicine in 1941 and entered the military service in September 1942. As a memorial, his father has established the Dr. Jerome D. Solomon Memorial Research Foundation.

VETERANS ADMINISTRATION

RESIDENCY TRAINING PROGRAMS

Two new residency training programs for physicians desiring to train in neurology under the Veterans Administration have been organized. These residencies offer training toward certification in neurology by the American Board of Psychiatry and Neurology.

The first new program will be conducted under the auspices of the New York University and the neurologic service of the psychiatric division of the Bellevue Hospital, New York. The program provides for training at Bellevue Hospital and the Veterans Administration New York Regional Office. Applications should be sent to Dr. S. Bernard Wortis, Chairman, Deans Subcommittee for Neurology, New York University, 400 East Thirtieth Street, New York.

The second new program has been organized by the George Washington School of Medicine and the Georgetown University Medical School. Residents will be offered training facilities at the Gallinger Municipal Hospital and the VA Hospital, Washington, D. C., the VA Regional Office, Childrens Hospital, and the Army Institute of Pathology. Applications should be forwarded to Dr. Walter Freeman, Chairman, Deans Subcommittee for Neurology, 2014 R Street N.W., Washington, D. C.

Other medical schools affiliated with the Veterans Administration for residency training in neurology where training programs are already under way, are:

Medical School	VA Hospitals and Clinics	Applications Received by
Cornell University Columbia University	Bronx, N. Y Hospital	Dean Willard C. Rappleye, 630 N 168th Street New York
Northwestern Univ. University of Illinois	Hines, Ill. Hospital	Dr Lewis J. Pollock, Northwestern University, Chicago
Univ. of Minnesota	Minneapolis	Dean Harold S. Diehl, University of Minnesota, Minneapolis 14
Boston University Tufts Medical College Harvard University	VA Hospital, Framingham, Mass.	Dr. Harry C Solomon, Chairman, Deans Subcommittee for Neuropsychiatry Harvard Medical School, Boston
Jefferson University Medical College and Clinic		Dr Edward A. Strecker, Chairman, Deans Subcommittee for Neuropsychiatry 111 North 49th Street, Philadelphia 39

EXHIBIT OF PROSTHETIC DEVICES

After more than a year's work in cooperation with the prosthetic appliances industry, which contributed most of the items at no expense to the government, a permanent exhibit of nearly a thousand items of prosthetic devices has been opened in the Veterans Administration building, Washington, D. C. Among the items on display are some three hundred and fifty different types of legs and arms, hearing aids, cosmetic hands, plastic eyes, wheel chairs, crutches, facial prosthetic devices, and wigs. The exhibit will enable prosthetic specialists in the Veterans Administration to make a critical analysis of the different features of the various aids and help veterans select the devices best suited to their needs. The exhibit should also aid in eliminating duplication of effort and research work in providing a central point at which inventors may learn what has already been developed in this field.

PATIENTS STUDY FROM TEXTBOOKS FLASHED ON CEILINGS

To patients flat on their backs for long periods such as those in tuberculosis hospitals and paraplegic centers, the Veterans Administration for the first time is bringing its educational program by flashing with special projectors microfilmed pages of textbooks on the ceilings over their beds. Thirty-two manuals have been microfilmed for the courses used in the Veterans Administration educational therapy program to launch this project. The subjects include English grammar, American government, physics, photography, refrigeration, radio for beginners, and books on the establishment and operation of small business. As patients complete the study of a page projected on the ceiling they turn the page by pressing a button on the projector to throw a new page on the ceiling. The special projectors were purchased by service organizations and similar groups throughout the country and were donated to the Veterans Administration without cost to the government. All Veterans Administration tuberculosis hospitals and paraplegic centers have several copies of each text film so that more than one veteran can study the same subject at the same time.

PERSONAL

Dr. Vernon C. Branham has been appointed assistant chief, outpatient section, Neuropsychiatry Division at the Central Office, Washington, D. C. Dr. Branham formerly was deputy commissioner of correction in New York, director of the New York State and City commissions for mental hygiene, and more recently director of the Woodbourne Institution for defective delinquents in New York.

PUBLIC HEALTH SERVICE

DR. MOUNTIN APPOINTED ASSISTANT SURGEON GENERAL

Dr. Joseph W. Mountin has been appointed associate chief, Bureau of States Services, U. S. Public Health Service, with the rank of assistant surgeon general, replacing Dr. Herman E. Hilleboe, who recently became health commissioner of New York. Dr. Mountin, who was formerly chief of the Division of States Relations in the Bureau of State Services, will be associate chief of the bureau and will continue to emphasize assistance to states for the development of full time local health departments. He joined the public health service in 1917 and in the last ten years has been in charge of several national divisions of the public health service, including the former Division of Public Health Methods, National Institute of Health and the former Division of Domestic Quarantine. He is a graduate of Marquette University School of Medicine, Milwaukee, and took part in the National Health Survey in 1935-1937, conducting the first mass study of hospital facilities in the United States.

RESEARCH FELLOWSHIPS

Under the research fellowship program of the U. S. Public Health Service, one hundred and sixty-one fellowships had been awarded to qualified scientists from 1945 when the program was inaugurated to May 6, 1947. The expansion of this program in the present fiscal year was made possible by increased Congressional appropriations for cancer, mental health and other research projects. The research fellowships advisory committee, composed of civilians, met at the National Institute of Health, Bethesda, Md, July 18, to advise the Surgeon General of plans to expand the research program

PERSONAL

With the approval of Surgeon General Parran, Dr. R. C. Williams, Assistant Surgeon General, has been appointed a member of the board of directors of the Music Research Foundation, Inc., a nonprofit organization which has for its purpose the study of the use of music in the treatment of disease. Dr Williams will act as chairman of the executive committee of the board of directors.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

ALABAMA

A New Ophthalmic Hospital.—Dr. Charles A. Thigpen, Montgomery, has presented to the Medical College of Alabama, Birmingham, $10,000 to be used to convert one floor in the Jefferson Hospital into an ophthalmic hospital, with operating rooms, museum, conference rooms and beds for patients. The gift is in memory of his nephew Dr. Job T. Cater, who was associated with him in practice until his death in 1940.

CALIFORNIA

Narcotic Violation.—Dr. Albert Peterson, 998 Page Street, San Francisco, pleaded guilty in the United States District Court at San Francisco to violation of the Federal Narcotic Law and on May 19 was sentenced to a term of five years.

Alameda County Blood Bank.—The Blood Bank of the Alameda County Medical Association has assumed full responsibility for the replacement of blood withdrawals. More than 700 pints is withdrawn each month. To maintain blood reserves, business, industrial, labor and club groups have been asked to establish blood credit plans. These plans are advance blood deposits on which group members may draw without posting a $25 replacement deposit. The objective of the plan is to maintain minimum monthly quotas for each group. Arrangements have been made with the American Womens Voluntary Services to provide free delivery for the blood. The board of directors asks each doctor to accept his share of community responsibility in seeing that his patients replace blood that he has withdrawn for them.

Personals.—Dr. Clesson Richardson and his wife, both San Francisco physicians, have left for Korea on the army hospital ship *Hope* to take charge of a general hospital for the Salvation Army at Yong Dong, 150 miles from Seoul. The Richardsons are the first Salvation Army representatives to be assigned to work in the Orient since the war. They went to Korea in 1940 to open this same hospital but returned because of Japanese opposition.——Dr. Leo Eloesser, San Francisco, formerly professor of clinical surgery at Stanford University School of Medicine, San Francisco, is returning to China on behalf of the World Health Organization Interim Commission. Dr. Eloesser was assigned as teaching specialist in surgery for the Chinese medical training program of the UNRRA in 1945 (The Journal, Sept. 29, 1945, p. 1049).

Postgraduate Courses for Practitioners.—Stanford University School of Medicine, San Francisco, in cooperation with the San Francisco Department of Public Health and the San Francisco Hospital, will hold postgraduate medical courses for practicing physicians September 8-12. Registration closes August 16. Morning courses will be on the subject of oncology, internal medicine, fractures and orthopedic problems and general problems in pediatrics. The afternoon courses will be on the subject of general surgery, general problems in surgical specialties, management of diabetes and obesity, and neurology and psychiatry. A course in anesthesiology, limited to eight physicians whose practice already includes anesthesiology, will also be offered. Subjects for evening meetings are body fluids and their replacement, chemotherapy and antibiotics, and hematology. The registration fee is $50.

COLORADO

Short Course in Chest Diseases.—A two week postgraduate course in chronic chest diseases, presented by the American Trudeau Society and the University of Colorado School of Medicine, began July 28 at the Colorado Medical Center, Denver, with special emphasis on tuberculosis. Thirty-five physicians from twelve states are enrolled. The instructors are members of the school of medicine faculty, three physicians from the Denver County Medical Society and nine visiting faculty members.

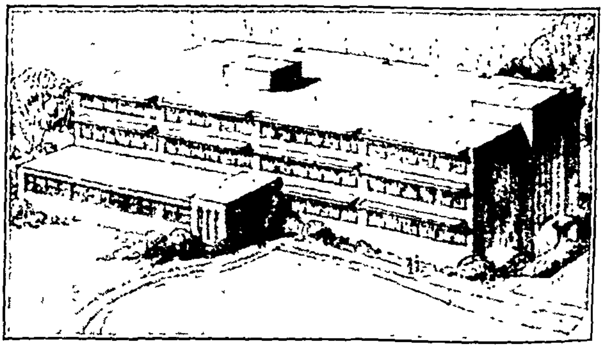
CONNECTICUT

Home Town Medical Care.—The contract between the Connecticut State Medical Society and the Veterans Administration to provide home town medical care for the state's war veterans has been renewed for one year. It has also been announced by the Veterans Administrations that its contract with the Connecticut Pharmaceutical Association has been renewed for the same period.

Rural Medical Service.—A recent poll of opinions from the general public conducted by the Connecticut State Medical Society's Committee on Rural Medical Service indicates that rural residents desire more medical specialists in the smaller towns, more hospital beds and the extension of hospital care plans. Other opinions thus expressed, according to Dr. Creighton Barker, secretary of the state medical society, comprise a general feeling among rural residents that the costs of medical care, although high, have not outrun other necessary costs of living, and an expression favoring the coordination of the home nursing services of various agencies. The report was made before 125 representatives of civic, farm and health agencies who attended Connecticut's first rural health conference July 16 at the University of Connecticut, New Haven.

ILLINOIS

Tuberculosis Research Center to Supply BCG Vaccine.—Governor Green has signed a bill authorizing the construction and maintenance of a tuberculosis research hospital in conjunction with the University of Illinois College of Medicine, Chicago. It includes an appropriation of $361,250. The Institute for Tuberculosis Prevention, which will be built on the medical campus and be run in close cooperation with the City of Chicago Municipal Tuberculosis Sanitarium, will supply BCG vaccine for the U. S. Public Health Service, now carrying on a project in Columbus, Ga., for a long range study of the vaccine. The vaccine, which can now be manufactured at a cost of about half a cent per dose, will be distributed to regular health agencies, city, state and federal, but not on commercial lines. The Research Foundation board headed by Park Livingston, president of the trustees of the University of Illinois College of Medicine, Chicago, has been set up to raise additional funds for operation of the institute. Among those associated with him are Dr. Walter H. Theobald, head of the mayor's medical center commission; Dr. Ernest E. Irons, Rush professor of medicine (emeritus); Dr. Robert Black, head of the department of pediatrics at Loyola University; Dr. Alexander A. Day, head of the department of bacteriology at Northwestern University, and Dr. Michael F. McGuire, clinical professor of surgery at Loyola University School of Medicine.



Architect's drawing of the institute.

Chicago

Coeducational School for Nurses.—Mount Sinai Hospital will conduct a coeducational school for nurses accredited by the Illinois State Department of Registration, beginning September 3. All applications should be in the registrar's office one month prior to this date. Last January 1 the hospital opened its new Nurses and Educational Building, which cost $825,000 to construct and $100,000 to equip.

Dr. Tom Spies to Head New Department.—Northwestern University and the Spies Committee for Clinical Research will establish in Chicago a center for medical research in the field of nutrition and metabolism. The agreement provides that Dr. Tom D. Spies, associate professor of medicine at the University of Cincinnati, will become professor of nutrition and metabolism and chairman of a new department in this field in the Medical School of Northwestern University. Following his resignation from the University of Cincinnati he will assume his new duties September 1, at which time the Spies Committee will sever its relationship with the University of Cincinnati. The agreement further provides that the committee will grant to the university at least $150,000 annually for five years to be used for the expenses of this department and for research carried on under Dr. Spies. The committee will shortly embark on a program to raise funds to house and endow the new department. The Spies Committee for Clinical Research was organized in 1943. Dr. Spies in 1937 organized, and has since directed, the University of Cincinnati studies in nutrition at the Hillman Hospital nutrition clinic, Birmingham, Ala., and this work will continue under his direction.

INDIANA

Dr. Zeller Appointed Director of Mental Health.—Dr. Charles A. Zeller, Lansing, Mich., began duties August 1 as director of the Indiana Council for Mental Health and superintendent of the Madison State Hospital, North Madison, succeeding Dr. Clifford L. Williams, resigned. Dr. Zeller, a graduate of the University of Buffalo School of Medicine, 1927, has served with state mental hospitals in Pennsylvania. In 1946 he was appointed director, Michigan Department of Mental Health.

KENTUCKY

Memorial to Dr. Owen.—Plans for a convalescent home for crippled children were announced early in June as a memorial to Dr. W. Barnett Owen, professor of orthopedic surgery at the University of Louisville School of Medicine who died February 23. Dr. Irvin Abell, professor emeritus of the School of Medicine, is chairman of the W. Barnett Owen Committee, which hopes to raise $150,000 to cover the cost of the home to be built on the grounds of the Kosair Crippled Children's Hospital in Louisville.

State Program for Handicapped Persons. — Practicing physicians and county health units have received letters from the division of special education of the department of education in Frankfort asking aid in administering the state program for physically and mentally handicapped persons. Funds are provided for surgery, hospitalization, medical treatment, purchases of artificial appliances and payment for employment training of persons who qualify for assistance. They must be over 16 years of age and have such impairments as blindness, deafness, cardiac disability, arrested tuberculosis or any crippled condition or physical abnormality constituting an employment handicap.

LOUISIANA

Personal.—Ralph E. Brauer, Ph.D., formerly on the faculty of Harvard Medical School, Boston, joined the faculty of the Louisiana State University School of Medicine, New Orleans, July 1, as assistant professor of pharmacology. He has received a grant of $5,000 from the National Institute of Health for research on the effect of liver injury on plasma proteins.

Cerebral Palsy Center.—The Orleans Unit of the Louisiana Society for Crippled Children has established a cerebral palsy center on the grounds of L'Union Francaise under the approval of the Orleans Parish Medical Society. It will be operated for the time being twice a month on the second and fourth Saturdays from 9 to 1 o'clock. The purpose of the center is to furnish instructions to the parents and guardians of spastic children in their care at home. No diagnosis or treatment will be given, nor will there be interference of duplication of treatment received by the children at clinics or from their private physicians. Dr. H. Theodore Simon is the medical adviser and Dr. Lyon K. Loomis the orthopedist.

MASSACHUSETTS

Appoint Professor of Preventive Medicine.—Dr. David D. Rutstein, New York, has been appointed professor of preventive medicine at Harvard Medical School, Boston, succeeding Dr. John E. Gordon, who since July 1, 1946, has been head of the department of epidemiology in the school of public health. Dr. Rutstein, a graduate of Harvard Medical School, 1930, served in the New York State Department of Health, first as a consultant in pneumonia and then as chief of the cardiac bureau. He has been an assistant professor of medicine at Albany Medical College and, on leave, an instructor in medicine at Columbia University College of Physicians and Surgeons, New York. During the war he was national director of the Gas Protection Section of the Office of Civilian Defense and was deputy commissioner of health for the New York City Health Department. Since 1946 he has been medical director of the American Heart Association and the American Council on Rheumatic Fever and a consultant to the Joint Research and Development Board of the departments of War and Navy.

MICHIGAN

Psychiatric Research Project.—The National Committee for Mental Hygiene, the Federal Office of Vocational Rehabilitation and the Michigan State Board of Control for Vocational Education will conduct a psychiatric research project in Wayne County. The staff, including a psychiatrist, clinical psychologist, psychiatric social work consultant, five psychiatric social workers and four clerks, will begin the project this fall under the supervision of the state rehabilitation division and the national committee. The results will be of value to science as well as to the future rehabilitation program for the mentally disabled.

Tuberculosis in Michigan.—Figures released by the state department of health show that tuberculosis took the lives of nearly twice as many men as women in Michigan in 1946. Male deaths due to tuberculosis numbered 1,214 and female deaths 629. More than 45 per cent of tuberculosis deaths among women occurred under 30 years of age, while 49 per cent of tuberculosis deaths among males occurred over 50 years of age. The Michigan trend is similar to national figures in this regard. The greatest number of female deaths were between the ages of 20 and 30, and the greatest number of male deaths over 60. Of the total of 1,843 deaths attributable to tuberculosis, 64 were of children under 5 years of age and 20 of these were children under 1 year. The death rate due to tuberculosis is 33.4 per hundred thousand of population and does not vary greatly from the previous five year average of 32.6 per hundred thousand.

MINNESOTA

Father and Five Sons Open Clinic.—Dr. William F. C. Heise, Winona, with his five sons, all physicians, opened a clinic in Winona July 7, where he has been practicing since 1898. The oldest son, Herbert, a graduate of Jefferson Medical College, Philadelphia, specializes in surgery. Dr. William, a graduate of Northwestern University Medical School, Chicago, is a pediatrician. Dr. Phillip, a graduate of the University of Arkansas School of Medicine, Little Rock, now a resident in obstetrics and gynecology, will join the staff in November. Dr. Paul, a graduate of Marquette University School of Medicine, Milwaukee, specializes in pathology and surgery. The fifth son, Dr. Carl, a graduate of Jefferson Medical College, was a resident physician on the eye, ear, nose and throat service at St. Luke's Hospital, Chicago. Winona has a population of about 22,490.

MISSISSIPPI

Deadline Near for Medical Scholarships.—August 15 is the deadline for receipt of applications for scholarship loan grants to become effective in September and October, and August 20 is the deadline for receipt of all credentials for applications filed by or before August 15 with the State Medical Education Board. At its last few meetings the board approved 13 more scholarship loans effective during the summer and fall of 1947, making a total of 73 loans approved to date. These 73 students who are preparing to return as general practitioners to rural areas in Mississippi will attend thirteen medical schools throughout the nation. Among these are seven women and eight Negroes. Forty-two of the students are veterans of World War II.

NEW YORK

Postgraduate Instruction.—The Medical Society of the State of New York and the New York State Department of Health have arranged two postgraduate lectures, one for Suffolk County Medical Society at Irving House, Southampton, Long Island, for July 30. Dr. James W. Hinton, associate clinical professor of surgery, Columbia University College of Physicians and Surgeons, spoke on "The Surgical Treatment of Hypertension." Postgraduate instruction for the Cayuga County Medical Society will be given at the Osborne Hotel, Auburn, September 18 at 8:30 p. m. William F. Bale, Ph.D., associate professor of radiology, University of Rochester School of Medicine and Dentistry, will speak on "Medical Aspects and Hazards of Controlled Nuclear Energy."

New York City

Two New Directors of Services. — Dr. A. Benson Cannon, professor of dermatology at Columbia University College of Physicians and Surgeons, began serving July 3 as director of the dermatology service at Presbyterian Hospital, succeeding Dr. J. Gardner Hopkins. Dr. Cannon was acting director of the dermatology clinic at the hospital from 1942 to 1946. Dr. Edmund P. Fowler Jr. succeeds Dr. John D. Kernan as professor of otolaryngology and director of the ear, nose and throat service at the Columbia-Presbyterian Medical Center. He took his medical degree at Columbia University College of Physicians and Surgeons, New York, 1930, and has been assistant attending otolaryngologist at Presbyterian Hospital since 1938. During the late war his work in aviation medicine and studies of diseases of the ear in military personnel won him the Legion of Merit award.

Affiliation with Institute for Rehabilitation Program.—The affiliation between Columbia University College of Physicians and Surgeons and the Institute for the Crippled and Disabled to develop a program of rehabilitation and reeducation of the disabled was announced July 7. The new agreement will provide a means for training physicians, technicians, nurses, psychologists, social workers, vocational councilors, educators and those of other related professions. The institute will continue its independent existence. Cooperation with community groups, universities, medical schools, hospitals and institutions in addition to Columbia will be continued and encouraged. Columbia will nominate the medical board of the institute. Dr. Frank E. Stinchfield, associate in surgery at Columbia, will head the institute's medical services as orthopedic surgeon in charge. Two assistant medical directors and a staff of medical consultants will be named to conduct the expanded medical program of the institute.

Appoint Dr. Sulzberger Director of Department.—Dr. Marion B. Sulzberger, assistant clinical professor of dermatology and syphilology, New York Postgraduate Medical School and Hospital at Columbia University, has been appointed professor of clinical dermatology and syphilology of the New York Postgraduate Medical School and director of the department of dermatology and syphilology of the New York Skin and Cancer Unit. He succeeds Dr. George M. MacKee, who is retiring and has been made professor emeritus of the medical school. Dr. Sulzberger received his medical degree from the University of Zurich in Switzerland in 1926. He was on the staff of the Dermatology Clinic at the University of Switzerland and the University Clinic of Breslau, Germany. He was an assistant attending physician at the New York Postgraduate Hospital as well as on the staff of the New York Skin and Cancer Hospital and a research associate in medicine at Columbia University. He has served on the board for the Society of Investigative Dermatology since 1937.

PENNSYLVANIA

Academy of Physical Medicine.—At the regular monthly meeting of the Pennsylvania Academy of Physical Medicine in Philadelphia, June 19, a symposium on backache was presented by three Philadelphia physicians, Drs. Henry T. Tumen on the medical aspects, Michael Scott on the neurosurgical aspect and Abraham M. Rechtman on the orthopedic aspect. Officers elected for the ensuing year are Drs. Harold Lefkoe, Philadelphia, president; William Schmidt, Philadelphia, vice president; Herman L. Rudolph, Reading, secretary and John H. Hennemuth, Emmaus, treasurer.

Philadelphia

New Head of Ophthalmology Department.—Dr. Glen G. Gibson, Philadelphia, has been appointed professor and head of the department of ophthalmology at the Temple University School of Medicine and Hospital, succeeding Dr. Walter I. Lillie, who died February 21. Dr. Gibson, a graduate of St. Louis University School of Medicine, St. Louis, in 1930, has been an associate professor of ophthalmology at Temple University School of Medicine. He interned at Providence Hospital, Detroit, and was a fellow in ophthalmology at the Mayo Clinic, Rochester, Minn., 1931-1934.

Second Epidemic Among Infants.—For the second time in six months the maternity ward of the Philadelphia General Hospital has been closed to new patients because of an outbreak of gastroenteritis which has caused two deaths. The decision to close the ward was taken at a conference between Bernard Segal, inspector of the bureau of communicable diseases of the city health department, and physicians at the hospital. Dr. Rufus S. Reeves, city director of public health, said that gastroenteritis appeared in the infant ward on June 23. Earlier this year 27 babies died in eastern New Jersey and Pennsylvania, with most of the cases originating in Allentown, Pa. (The Journal, May 17, p. 307).

Begin Construction of Cancer Research Laboratory.—The Institute for Cancer Research, Inc., Philadelphia, broke ground early in June for the construction of a laboratory costing more than $1,000,000 at Fox Chase. Ground for the institute, which was formed three years ago, is being provided by Jeanes Hospital for a period of ninety-nine years. The hospital will cooperate with the institute technically. Funds will be donated by J. Howard Pew, J. N. Pew, Miss Ethel Pew and Mrs. Mabel Pew Myrin. The main laboratory will house 100 research workers in its three stories and basement. The Lankenau Research Institute building will continue to be used by the Institute for Cancer Research when its new building is completed in about a year. The Institute for Cancer Research, Inc., while a separate legal corporation, will continue with the staff of Lankenau Research Institute, which has been engaged in cancer research and associated diseases for more than twenty-five years. Dr. Stanley P. Reimann will continue as its director.

TEXAS

Gift to Rehabilitation Clinic.—In recognition of the work of the staff of the John Sealy Hospital, Galveston, in connection with the Texas City disaster victims, the Monsanto Chemical Company of St. Louis has given a grant of $25,000 to assist in the development of a Rehabilitation Clinic at the University of Texas Medical Branch, Galveston. Other industrial concerns in the Texas City-Galveston area are also assisting in the development of the project. The clinic will be developed in accordance with the recommendations of the Baruch Committee for Physical Medicine and will involve the services of orthopedic surgery, neurosurgery, plastic surgery, physical and occupational therapy, psychologic guidance, social readjustment and job placement.

Dr. Rigdon to Head Laboratory.—Dr. Raymond H. Rigdon, professor of pathology at the University of Arkansas Medical School, has accepted appointment as professor and director of the laboratory of experimental pathology at the University of Texas Medical Branch, Galveston. Dr. Rigdon received his M.D. degree from Emory University School of Medicine, Atlanta, Ga., 1931. Following a residency in pathology at Duke University School of Medicine, Durham, N. C., he became assistant professor of pathology at Vanderbilt Hospital, Nashville, Tenn. He was an associate professor of pathology at the University of Tennessee, 1939-1944, before going to the University of Arkansas. Dr. Rigdon is chairman of the southwestern section of the Society for Experimental Biology and Medicine.

WEST VIRGINIA

Care of Poliomyelitis Patients.—A training program designed to provide improved service for poliomyelitis patients in hospitals has been instituted by the Kanawha County chapter of the National Foundation for Infantile Paralysis. Several poliomyelitis emergency volunteers have completed a theoretical course and are now receiving bedside training at the Marmet Hospital, Marmet, and at Morris Memorial Hospital for Crippled Children at Milton. They will assist doctors, nurses and physical therapists in the care of patients. The program in Kanawha County is under the direction of Mrs. Fred Sarles, Charleston, the National Foundation's assistant director of women's activities in West Virginia. Instructions are being given by physicians active in the program.

Dr. Rossman to Head Bureau of Mental Health.—Dr. William B. Rossman, Charleston, has been appointed director of the new bureau of mental health of the state department of health. Plans for the new bureau were completed by the Public Health Council at a meeting in Charleston June 30. The establishment of mental clinics in various parts of the state is part of the program being planned. No appropriation was made by the legislature, but one third of the expenses will be paid from the state health department's general fund and the remainder will be provided by the federal government under provisions of the national mental health act passed by Congress in July 1946. Dr. Rossman, a graduate of Indiana University School of Medicine, Bloomington-Indianapolis, 1938, served in the ETO for two years as a neuropsychiatrist in the medical corps of the army.

FOREIGN

Paratyphoid Outbreak.—An outbreak of paratyphoid fever in a number of communities north of Wiesbaden, Germany, was reported July 3 from the office of the chief surgeon, U. S. Army Headquarters in Berlin, according to the Associated Press. Between 600 and 1,000 cases have been reported and the outbreak was believed spreading. It is said that locally produced milk was believed to be the source of infection.

Tuberculosis Increase in Germany.—According to the monthly report of General Lucius D. Clay, tuberculosis has increased more than 50 per cent in the American zone in Germany in the past year. About 14,500 patients with open tuberculosis have not been hospitalized because of lack of facilities. General Clay reports that the weekly average of new cases has increased from 923 in March to 1,259 in May. The known cases of active tuberculosis of the lung and larynx under medical supervision increased from 93,821 in July last year to 121,842 in April 1947. Of these the report said 35,539 were classed as open infectious cases. Slightly more than 21,000 beds are available for isolation in treatment of tuberculosis patients, the report said.

GENERAL

International Conference of Physicians.—The Royal College of Physicians of London is sponsoring an International Conference of Physicians September 8-13 in London. The scientific program, comprising nine sections, will be presented by authorities in the various specialties from Britain, the United States, Sweden, France, Switzerland, Norway, Denmark, the Netherlands, Belgium and Czechoslovakia. The speakers from the United States will be Dr. Helen B. Taussig, Baltimore, and Dr. Frank N. Wilson, Ann Arbor, before the section on cardiology; Dr. Franz J. Kallmann, New York, before the section on psychiatry, and Dr. John B. Grant, New York, before the section on social medicine. Admission to the conference is by invitation. Application must be made to the organizing secretary, Dr. Gordon B. Mitchell-Heggs, Royal College of Physicians, Pall Mall East, London, S. W. 1.

Resolution on Training in Anesthesiology.—The board of directors of the American Society of Anesthesiologists, Inc., June 11 in Atlantic City, adopted a resolution recommending (1) the establishment of departments of anesthesiology in all medical schools and hospitals under the direction of a doctor of medicine actively engaged in the practice of anesthesiology and (2) that the department of anesthesiology bear the same relationship to the medical school and/or hospital that is borne by other medical departments of the institution. The society also stated its disapproval of (1) the training of persons other than doctors of medicine in anesthesiology for the assumption of responsibility in the care of patients where it may be necessary to exercise medical judgment and particularly of the issuance of certificates for such training by its members and (2) the existence of departments of anesthesiology in hospitals and/or medical schools under the direction of persons other than doctors of medicine or under the nominal direction of doctors of medicine not actively engaged in the practice of anesthesiology.

American Congress of Physical Medicine.—The twenty-fifth annual scientific session and instruction course of the American Congress of Physical Medicine will be held September 2-6 at the Hotel Radisson, Minneapolis. Among many others, the following physicians will address the scientific sessions:

Khalil G. Wakim, Rochester, Minn., The Effects of Artificial Fever on the Circulation in Man.
Frederick A. Jostes, St. Louis, Back Manipulations.
Daniel J. Leithauser, Detroit, Early Ambulation and Related Procedures in Surgery.
James B. Mennell, London, England, Manipulation of the Joints of the Upper Extremity.
Frederic T. Jung, Chicago, Physical Physiology as a Basis for Physical Medicine.
Carl M. Peterson, Chicago, Physical Medicine in Industrial Insurance Practice.
Hart E. Van Riper, New York, A Challenge to Physical Medicine.
Robert E. Priest, Minneapolis, Results of Tracheotomy in Bulbar Poliomyelitis.
Abe B. Baker, Minneapolis, Pathology of Changes in Bulbar Poliomyelitis.

In addition to the scientific sessions the annual instruction courses will be held September 2-5 and will be open to physicians and therapists registered with the American Registry of Physical Therapy Technicians. For further information address the American Congress of Physical Medicine, 30 North Michigan Avenue, Chicago 2.

Admiral McIntire to Head Red Cross Blood Program.—Vice Admiral Ross T. McIntire, formerly surgeon general of the navy, has been named director of the new national blood program of the American Red Cross, which contemplates providing blood and its derivatives without cost to the entire nation. The blood program, patterned on methods employed during the war to procure blood donations for the armed forces, was approved by the Red Cross board of governors at a meeting in Cleveland in June. The program is being undertaken in direct response to the need of the medical profession for blood in saving lives as well as in the treatment and prevention of disease. The Red Cross plans call for the collection of blood at strategic centers throughout the country as well as by mobile units operating in rural areas. At the program peak an estimated 3,000,700 blood donations will be required annually. The five operations in connection with the blood program are (1) collecting blood, (2) processing it for use as whole blood and blood derivatives, including packing and storage, (3) distributing the blood and blood products, (4) making blood available for continuous research and investigation and (5) maintaining the high standards set in this field. During the first year of operation the Red Cross contemplates the establishment of twenty to twenty-five centers. The program will be financed through contributions made by the American people. It is estimated that from three to five years will be required before it is in full operation. Cost of the operation of the centers will be shared on an equitable basis between the national organization and the chapters.

Prevalence of Poliomyelitis.—Reports of cases of poliomyelitis for the periods indicated have been received from the division of public health methods, U. S. Public Health Service:

CORRECTION

Discussion at National Conference on Rural Health.—In the proceedings of the National Conference on Rural Health published in The Journal March 22, page 862, the discussion credited to Mr. Graham L. Davis, Michigan, should have been credited to Mr. Michael M. Davis, New York City.

Marriages

Allan Horace Warner, Woodside, N. Y., to Miss Tonya Jetti Morgenstern at Brooklyn April 20.

Neil Esposito, Brooklyn to Miss Regina F. Van Guilder of Rutland, Vt., in Passaic, N. J., April 12.

John W. Ketchersid, Ardmore, Okla., to Mrs. Mabel D. Haire at Springtown, Texas, May 14.

Deaths

Warren Beagle Davis ⊕ Philadelphia; born in Jessamine County, Ky., Sept. 6, 1881; Jefferson Medical College of Philadelphia, 1910; specialist certified by the American Board of Otolaryngology; member of the founders group of the American Board of Plastic Surgery; clinical professor of plastic and reconstructive surgery at his alma mater; member of the American Society of Plastic and Reconstructive Surgery, serving as a member of the board and in 1936-1937 as president; fellow of the American College of Surgeons, College of Physicians of Philadelphia, Academy of Surgery of Philadelphia, American Academy of Ophthalmology and Otolaryngology and the American Laryngological Association; member of the American Association of Anatomists and the Association of Military Surgeons of the United States; during World War I served on the medical advisory board of the War Department for Pennsylvania and later as captain in the medical corps of the U. S. Army, where he had been in charge of the school of maxillofacial surgery at Camp Greenleaf, Fort Oglethorpe, Ga.; during World War II served as a member of the National Faculty of Plastic and Maxillofacial Surgery, appointed by the Surgeon General; on the staffs of the Jefferson and Frankford hospitals and the Kensington Hospital for Women; in 1938 received an honorary degree of doctor of science from Georgetown College, Georgetown, Ky.; in 1942 president of the alumni association of Jefferson Medical College; since 1941 member of the state board of plastic surgery, commonwealth of Pennsylvania; editor of *Plastic and Reconstructive Surgery;* died July 7, aged 65, of hypertensive cardiovascular disease.

Mathew Aaron Reasoner ⊕ Colonel, U. S. Army, retired, Alton, Ill.; born in New London, Iowa, Nov. 1, 1875; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1899; Army Medical School in 1906, Army Industrial College in 1929 and the Medical Field Service School, Advanced Course, in 1930; served as physician for the Mexican Central Railroad; entered the medical corps of the U. S. Army as a first lieutenant in 1906; promoted through the various grades to that of colonel in 1932; retired Nov. 30, 1939; during World War I served overseas and with the Army of Occupation; served as chief surgeon in the department of the Philippines and had been corps area surgeon for the Sixth Corps Area in Chicago; assistant professor, Army Medical School, from 1914 to 1917; during World War II recalled to active duty and assigned as professor of military science and tactics at St. Louis University School of Medicine, where he became professor emeritus in 1946 and where he served in the department of public health; fellow and formerly member of the board of governors of the American College of Surgeons; died in St. Joseph's Hospital June 20, aged 71, of cerebral hemorrhage.

Harry Hampton Donnally ⊕ Washington, D. C.; born in Georgetown, Ky., Sept. 4, 1877; Columbian University Medical Department, Washington, D. C., 1903; for many years professor and executive officer, department of pediatrics, at George Washington University School of Medicine, where he had been professor emeritus of pediatrics since 1943; specialist certified by the American Board of Pediatrics; fellow of the American Academy of Pediatrics serving as state chairman for the District of Columbia and the American Academy of Allergy; past president of the Society for the Study of Asthma and Allied Conditions; member of the Washington Academy of Medicine, the Clinico-Pathological Society and the George Washington Medical Society; for many years a member of the staff of the Children's Hospital, where he was a founder and director of the allergy clinic; attending physician for the Columbia Institution for the Deaf for many years; consulting pediatrician for Columbia Hospital, Gallinger Municipal Hospital and Glenn Dale (Md.) Sanatorium; died in Baltimore May 23, aged 69, of pneumonia.

Clarence Edward Skinner ⊕ Darien, Conn.; born in New Haven, Conn., June 8, 1868; Yale University School of Medicine, New Haven, 1891; charter member and formerly vice president of the American Roentgen Ray Society; fellow of the New York Academy of Medicine; at one time physician in charge of the Newhope Private Sanitarium in New Haven, where he had been a director; secretary of the board of directors and medical superintendent of the Elm City Private Hospital; served as medical director of the Postal Life Insurance Company of New York and of the eastern division of the Western Union Life Insurance Company of Spokane, Wash., with headquarters in New York; for many years medical examiner in chief and consultant at the home office of the New York Life Insurance Company; died April 24, aged 78, of coronary occlusion.

Archie Marvin Roberts ⊕ Los Angeles; born in Brandon, Texas, Aug. 8, 1902; Stanford University School of Medicine, San Francisco, 1929; assistant professor of medicine at the University of Southern California School of Medicine; specialist certified by the American Board of Internal Medicine; fellow and life member of the American College of Physicians; member of numerous societies; president of the Los Angeles Heart Association; chairman of the heart division, advisory committee of the Los Angeles Tuberculosis and Health Association; attending physician at the Los Angeles County Hospital, general staff member of the Good Samaritan Hospital and associate staff member at St. Vincent's Hospital; died April 1, aged 44, of coronary disease.

Frederick Wooten Wilkerson ⊕ Montgomery, Ala.; born in Montgomery, Ala., Aug. 19, 1885; Columbia University College of Physicians and Surgeons, New York, 1909; specialist certified by the American Board of Internal Medicine; fellow and governor for many years of the American College of Physicians; member of the House of Delegates of the American Medical Association in 1920; served during World War I; past president of the Medical Association of the State of Alabama; member of the American Heart Association, Southern Medical Association and the Southern Interurban Clinical Club; on the staff of St. Margaret's Hospital; died April 24, aged 61, of hypertensive cardiovascular disease.

Charles Alford Maghy, San Diego, Cal.; born in Lucan, Ont., July 30, 1884; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905; member of the American Medical Association, American Academy of Ophthalmology and Otolaryngology, Pacific Coast Oto-Ophthalmological Society, Oxford Ophthalmological Congress and the Ophthalmological Society of England, Ireland and Scotland; formerly associate professor of ophthalmology at his alma mater; specialist certified by the American Board of Ophthalmology; on the staff of the Mercy Hospital, where he died April 27, aged 62, of coronary embolism.

Henry John Storrs ⊕ St. Louis; born in 1877; Johns Hopkins University School of Medicine, Baltimore, 1904; assistant professor of clinical gynecology and obstetrics at St. Louis University School of Medicine, where he had formerly been instructor and senior instructor in gynecology and obstetrics; instructor in obstetrics at his alma mater from 1907 to 1909; instructor in obstetrics and gynecology at the Washington University School of Medicine in St. Louis from 1910 to 1916; for many years on the staff of the Maternity Hospital; served on the staffs of St. Luke's and Bethesda General hospitals; died in West Chester, Pa., April 21, aged 70, of coronary thrombosis.

George Howitt Weaver ⊕ Wilmette, Ill.; born at Sussex, Wis., Oct. 2, 1866; Rush Medical College, Chicago, 1889; formerly professor of pathology at his alma mater and at the Northwestern University Woman's Medical School in Chicago; past president of the Society of Medical History of Chicago; fellow of the Association of American Physicians; member of the American Association of Pathologists and Bacteriologists and the Chicago Pathological Society; for many years on the staffs of the Memorial Institute for Infectious Diseases and the Cook County Hospital; died in Evanston April 19, aged 80, of perforated duodenal ulcer with peritonitis.

Arthur Morris Zinkhan ⊕ Washington, D. C.; born in 1890; Georgetown University School of Medicine, Washington, D. C., 1912; specialist certified by the American Board of Otolaryngology; formerly associate professor of otolaryngology at his alma mater; member of the American Academy of Ophthalmology and Otolaryngology and the American Laryngological, Rhinological and Otological Society; fellow of the American College of Surgeons; served in the Russian army and later in the U. S. Army during World War I; on the staff of the Episcopal Eye, Ear and Throat Hospital; died April 30, aged 56, of coronary thrombosis.

Frances Fenton Cattell Ancell, Tujunga, Calif.; Woman's Medical College of Pennsylvania, Philadelphia, 1896; for many years a medical missionary in China; died April 13, aged 80, of carcinoma of the rectum and coronary sclerosis.

Benjamin F. Brandt ⊕ Cappeln, Mo.; Washington University School of Medicine, St. Louis, 1908; died April 29, aged 65, of coronary occlusion.

Nathan Bronfeld, Los Angeles; Loyola University School of Medicine, Chicago, 1916; member of the American Medical Association; died April 10, aged 62, of coronary sclerosis.

Joel Daniel Brown, Upper Darby, Pa.; Jefferson Medical College of Philadelphia, 1904; died February 3, aged 68, of bronchiectasis.

Ralph Alonzo Bunn, Dayton, Ohio; Miami Medical College, Cincinnati, 1900; died in Clearwater, Fla., April 14, aged 70, of coronary occlusion.

James M. Campbell, Goldthwaite, Texas; University of Texas School of Medicine, Galveston, 1896; member of the American Medical Association; vice president of the State Medical Association of Texas; past president of the Brown-Comanche-Mills-San Saba Counties Medical Society; served on the local Selective Service board during World War I and II; for many years surgeon for the Santa Fe Railway; died March 24, aged 73, of carcinoma.

Bertram Horace Caswell ✠ Somerville, Mass.; Tufts College Medical School, Boston, 1903; member of the New England Otological and Laryngological Society; served during World War I; served on the staffs of St. Elizabeth's and Massachusetts General hospitals in Boston; died in the Veterans Administration Hospital in Boston April 14, aged 72, of cerebral hemorrhage.

Gerritt Cotts ✠ Chicago; Rush Medical College, Chicago, 1921; fellow of the American College of Surgeons; on the staffs of the Augustana and Ravenswood hospitals, where he died May 13, aged 58, of heart disease.

Leo Allen Dermody, Omaha; John A. Creighton Medical College, Omaha, 1908; died April 5, aged 63.

George S. Dowell ✠ Braymer, Mo.; University Medical College of Kansas City, 1900; past president of the Caldwell-Livingston Counties Medical Society; died April 22, aged 71, of cerebral thrombosis.

Edward Morris Fahnestock ✠ Gulfport, Miss.; Louisville (Ky.) Medical College, 1897; served as county physician; killed April 2, aged 75, when the automobile in which he was driving was struck by a train.

Madison Aaron Furrh ✠ Major, U. S. Army, retired, Elysian Fields, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1935; interned at the Southern Baptist Hospital in New Orleans; entered the medical corps of the U. S. Army in November 1939; promoted to captain in November 1942; served during World War II; retired for disability in line of duty May 31, 1944 with the rank of major; killed in an automobile accident near Prescott, Ariz., March 18, 1946, aged 36.

Francis Ward Glann, Climbing Hill, Iowa; Sioux City College of Medicine, 1898; died April 20, aged 85, of senility.

John Dryer Green ✠ McPherson, Kan.; University of Nebraska College of Medicine, Omaha, 1931; medical missionary to China under the Free Methodist Church in charge of the Grinnell Memorial Hospital, Kihsien, Honan Province, China, from 1932 to 1938; died May 11, aged 44, of hypertension and nephritis.

Vivian Carsdale Hamilton, Oakland, Calif.; College of Medical Evangelists, Los Angeles, 1924; died April 15, aged 56, of a disease causing generalized adenopathy and obstruction of the lymph ducts.

Franklin Pierce Hannon, Rochester, N. Y.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1889; served during World War I; died in the Veterans Administration Hospital in Bath April 6, aged 81, of lobar pneumonia.

Ralph Emerson Henry ✠ Lieutenant Colonel, U. S. Army, retired, De Land, Fla.; University of Wooster Medical Department, Cleveland, 1910; U. S. Army Medical School in 1924; served during World War I; entered the medical corps of the U. S. Army with the rank of captain on July 1, 1920; retired with the rank of lieutenant colonel on Sept. 30, 1937 for disability in line of duty; died March 15, aged 61, of coronary thrombosis.

Carl M. Johnson ✠ Dawson, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1910; councilor of the Third District of the Minnesota State Medical Association; superintendent and director of the Dawson Hospital; died recently, aged 64.

Braxton Bynum Lloyd, Chapel Hill, N. C.; University of North Carolina School of Medicine, Raleigh, 1909; served as member of the board of directors of the Bank of Chapel Hill for many years; formerly mayor of Carrboro; died March 20, aged 60.

Ora Lee McCay, Romney, Ind.; Medical College of Indiana, Indianapolis, 1904; member of the American Medical Association; past president of the Tippecanoe County Medical Society; formerly county health commissioner; served during World War I; major, medical reserve corps, not on active duty; affiliated with the Home Hospital in Lafayette; died April 17, aged 67, of hypostatic pneumonia, chronic myocarditis and nephritis.

Alvin Oren McClelland, Youngstown, Ohio; University of Pittsburgh School of Medicine, 1894; died in the Mount Sinai Hospital in Cleveland March 27, aged 77, of prostatic hypertrophy.

Clara Louise McCord, Philadelphia; Maryland Medical College, Baltimore, 1913; died February 8, aged 61, of coronary occlusion.

Clyde A. Medlar, Verdon, Neb.; Northwestern University Medical School, Chicago, 1905; past president of the Richardson County Medical Society; served on the school board and as mayor; affiliated with Our Lady of Perpetual Help Hospital; died in Omaha April 1, aged 68, of coronary disease.

John Joseph Melvin ✠ Oakland, Calif.; Creighton University School of Medicine, Omaha, 1927; died April 6, aged 45, of myocardial infarction.

Frank John Miller, Pineville, Va.; University of Vermont College of Medicine, Burlington, 1894; member of the American Medical Association; affiliated with the Rockingham Memorial Hospital in Harrisburg, where he died April 13, aged 78, of carcinoma of the head of the pancreas.

Lewis Hitchner Miller, Woodstown, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1895; member of the American Medical Association; on the staff of the Salem County Memorial Hospital, Salem; died April 8, aged 78, of coronary disease.

James Liguori Moriarty ✠ Milford, Conn.; Harvard Medical School, Boston, 1896; fellow of the American College of Surgeons; served during World War I; on the staffs of St. Mary's and Waterbury hospitals in Waterbury; died April 3, aged 75, of chronic myocarditis.

Joseph Henry Myers, Jackson, Mich.; Homeopathic Hospital College, Cleveland, 1893; died in Philadelphia April 15, aged 77, of coronary thrombosis.

James Donaldson Parker ✠ Fayette, Iowa; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1892; past president of the Fayette County Medical Society; died April 18, aged 79, of coronary thrombosis.

Charles Frederick Pettibone, Indiana, Pa.; Jefferson Medical College of Philadelphia, 1889; died February 7, aged 81, of mesenteric thrombosis.

Ray Emmett Alfred Pomeroy ✠ Medical Director, Captain, U. S. Navy, Washington, D. C.; University of Oregon Medical School, Portland, 1916; U. S. Naval Medical School, 1925; fellow of the American College of Surgeons; entered the U. S. Navy on Jan. 28, 1922; died Nov. 4, 1946, aged 52, of coronary thrombosis.

John Purdy, Philadelphia; Jefferson Medical College of Philadelphia, 1896; served during World War I; died in the U. S. Naval Hospital February 11, aged 76, of coronary sclerosis and bronchopneumonia.

William Perry Reaves, Greensboro, N. C.; University of the South Medical Department, Sewanee, Tenn., 1903; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; died in Winston-Salem, April 2, aged 71, of cardiovascular renal disease.

Ernest Slemmons Reedy ✠ Seattle; Marion-Sims College of Medicine, St. Louis, 1898; served during World War I; on the staffs of the Doctors and Harborview hospitals; died April 9, aged 75, of dissecting aneurysm of the aorta.

Jesse Lilly Saddler, Lagrange, Ohio; Cleveland Homeopathic Medical College, 1905; member of the American Medical Association; served during World War I; formerly mayor of Bay Village; treasurer of Lagrange; served on the staff of the Memorial Hospital in Elyria; died April 9, aged 72, of lobar pneumonia.

Otho Daniel Schaul, Philadelphia; Jefferson Medical College of Philadelphia, 1892; died February 4, aged 78, of intestinal obstruction.

Charles Cicero Shaw, Oklahoma City; Eclectic Medical University, Kansas City, Mo., 1905; Kansas City College of Medicine and Surgery, 1916; also a graduate in law; formerly state senator; served overseas during World War I; died April 3, aged 69, of pneumonia.

John Edward Smaltz ✠ Media, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1929; served overseas during World War II; affiliated with the Graduate Hospital of the University of Pennsylvania in Philadelphia, where he had been connected with the Presbyterian and Methodist hospitals; on the staffs of the Media (Pa.) Hospital and the Chester and Crozer hospitals in Chester; died April 18, aged 47.

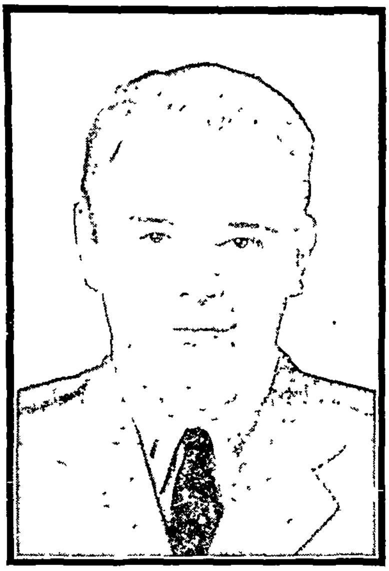
Erwin David Spiegl, Lynn, Mass.; Deutsche Universitat Medizinische Fakultat, Prague, Czechoslovakia, 1928; member of the American Medical Association; on the staff of the Lynn (Mass.) Hospital and the Beth Israel Hospital in Boston, where he died April 6, aged 45, of acute myocardial infarction.

Archibald Redd Stone ⊕ Columbus, Ohio; Washington University School of Medicine, St. Louis, 1909; served during World War I; medical director and member of the board of directors for the Midland Mutual Life Insurance Company; died April 13, aged 60, of coronary thrombosis.

Arthur Ernest Strong, Altadena, Calif.; Syracuse University College of Medicine, 1898; served during World War I; formerly health officer of Mount Vernon, N. Y.; at one time on the staff of the Norwalk (Calif.) State Hospital; died April 5, aged 72, of bronchopneumonia.

Gilbert Bernard Tepper, Los Angeles; University of Illinois College of Medicine, Chicago, 1927; on the staff of the Queen of Angels Hospital, where he died April 4, aged 43, of heart disease.

Frank Adelbert Tinker, Lapeer, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1884; member of the American Medical Association; health officer; past president of the Lapeer County Medical Society; served as mayor, on the school board and as alderman; died April 8, aged 87, of pneumonia.



Lieut. (jg) Robert G. Rickert
(MC), U. S. N. R., 1915-1945

Capt. Ralph William Snodgrass
M. C., A. U. S., 1905-1946

Lieut. Charles G. Butler
(MC), U. S. N., 1913-1945

Albert Roling Tucker, Manistique, Mich.; Michigan College of Medicine and Surgery, Detroit, 1899; member of the school board; served during World War I; died April 1, aged 70, of heart disease.

Walter Jabez Weiser, Marion, Ohio; Eclectic Medical Institute, Cincinnati, 1894; served as county coroner and city health commissioner; served during World War I; died April 24, aged 76, of cerebral hemorrhage.

John Latham Wethered, Laurel, Md.; University of Pennsylvania Department of Medicine, Philadelphia, 1890; member of the American Medical Association; resident physician at the Laurel Sanitarium, where he died April 3, aged 79, of cerebral hemorrhage.

Robert William Wilcox ⊕ Seal Beach, Calif.; Stanford University School of Medicine, San Francisco, 1917; fellow of the American College of Surgeons; served during World War I; on the staffs of the Seaside and St. Mary's hospitals in Long Beach; died April 6, aged 56, of coronary occlusion.

Arthur John Wilkinson, Camarillo, Calif.; Detroit College of Medicine, 1901; veteran of the Spanish-American War and World War I; affiliated with the Camarillo State Hospital; died in the Mercy Hospital, San Diego, April 9, aged 68, of adenocarcinoma of the stomach with metastasis.

John Roy Williams, Palo Alto, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1903; served during World War I and later as surgeon in the U. S. Public Health Service; died April 15, aged 70, of coronary thrombosis

Walter Scott Wood, Trimble, Mo ; Marion-Sims College of Medicine, St. Louis, 1896; member of the American Medical Association; died March 31, aged 75, of arteriosclerosis.

Mordecai A. Worsham, Centerville, Ark.; Memphis (Tenn) Hospital Medical College, 1883; died in Wichita, Kan., April 6, aged 89, of arteriosclerosis.

KILLED IN ACTION

Robert Garfield Rickert, Ann Arbor, Mich ; University of Michigan Medical School, Ann Arbor, 1939; served an internship and residency at the Henry Ford Hospital in Detroit; at one time affiliated with the Veterans Administration in Dearborn; began active duty as a lieutenant (jg) in the medical corps of the U. S. Naval Reserve in August 1944; medical officer aboard the *Terror;* killed in action May 1, 1945, during the Okinawa campaign, aged 30.

Ralph William Snodgrass, Des Moines, Iowa; Rush Medical College, Chicago, 1932; interned at St. Luke's Hospital in Kansas City, Mo., and at St. Louis Maternity Hospital in St. Louis, where he also served a residency; served a residency at the Barnes Hospital in St. Louis; began active duty as a captain in the medical corps, Army of the United States, on Aug. 31, 1942; reported missing July 2, 1944 while en route to the Asiatic theater after the sinking of the *Jean Nicollet,* a liberty ship in the Indian Ocean; according to the War Department, presumptive date of death, as required by law, is Dec. 18, 1946, aged 39

Charles Gleason Butler ⊕ Lieutenant, U. S. Navy, Los Angeles; University of Southern California School of Medicine, Los Angeles, 1940; interned at the U. S. Naval Hospital in San Diego; entered the U. S. Navy in July 1940; assigned to the Asiatic Fleet; lost South of Java; presumed dead Nov. 25, 1945, aged 32, by the U. S. Navy Department.

The Protection of Workers Against Radioactive Substances

New rules for the protection of workers in radioactive substances are announced by the minister of labor. All persons working with or near luminous compounds must be examined within seven days of starting work, and thereafter at intervals of not more than one month. A health register to include all workers must be kept. Those engaged in the manipulation of luminous compounds must wear photographic film for one week in every three months. This is to check the sufficiency of other precautions, which include the prohibition of more than forty-eight hours of work a week, and provision for three months in other employment after each full year's employment on processing. Measures are also laid down for keeping the air and all surfaces free from luminous compounds and for protection by special clothing and by screening.

Streptomycin Treatment of Tuberculous Meningitis

In the hospitals there is a much greater demand for streptomycin for the treatment of tuberculous meningitis than the supply of the drug. This is not due to the belief that its value has been proved but to the fact that there is no other remedy for this hopeless disease. At first all supplies came from the United States, but three British firms have set up the complex plant required for its production. By next spring these hope to produce about 250 Gm. a month. As 350 Gm. is necessary for the treatment of 1 case, the British output can play little part in the treatment of the 1,500 to 2,000 cases which occur annually. In the face of this shortage the Medical Research Council has decided that all streptomycin reaching this country must be passed through its hands for the use of research workers. It has set up special units for streptomycin treatment at the Hospital for Sick Children, Great Ormond Street, Hammersmith Hospital, Guy's Hospital, the National Hospital for Nervous Diseases, Alder Ley Hospital, Liverpool, and the Royal Hospital for Sick Children, Glasgow. At these hospitals selected cases, mostly of tuberculous meningitis, are being treated under strictly controlled conditions.

A New Classification of Tuberculosis

The recommendations of the Joint Tuberculosis Council for the revision of the classification and terms to be used in annual returns have been adopted by the minister of health. Tuberculous patients will be divided into two classes, A and B, according to whether tubercle bacilli have not or have been recovered. Patients may be transferred at any time from class A to class B. But those from whom tubercle bacilli have not been recovered within the first eight weeks of observation should be placed in class A. Single positive bacteriologic reports, unconfirmed by further search and unsupported by clinical or x-ray evidence of tuberculosis, may be ignored.

Respiratory cases are to be further subdivided into three groups: group 1, in which constitutional disturbance is slight, and there are signs of x-ray changes; group 3, in which there is profound systemic disturbance or constitutional deterioration, and pronounced impairment of function; and group 2, which includes all cases that cannot be placed in groups 1 or 3.

An uncomplicated pleural effusion for which no other cause can be found should be regarded as tuberculous, and the case placed in group 1 of class A or B, according to the bacteriologic report on the fluid.

Measures Taken Against Quack Medicine

In view of the lately increased diffusion among the public of various treatments, often detrimental to public health and escaping the control of qualified scientific societies, the director for social hygiene has drawn up a report to the Ministry for Public Health recommending the creation of a consultative commission composed of selected and qualified members and of representatives of scientific organizations which would be entrusted with the study of those remedies.

The minister for public health has applied to the National Academy of Medicine for collaboration, and the latter has appointed a special commission, called the Quack Commission, on behalf of which at a recent meeting, Professor Leroux delivered a statement of the question. After a discussion to which, among others, Professors Dujarric de la Rivière, Bezançon, Brouardel and Rist took part, the academy decided on a course of action. It has agreed to depute a representative to the commission established by the minister which shall also have to deal with remedies which, though not being officially recognized, have nevertheless certain useful therapeutic properties. On the other hand, the academy has emphasized that, as formerly, it retains its entire liberty of studying by itself all questions concerning quack medicine, as it has done lately as regards cancer and tuberculosis. It has decided to exert a direct immediate action against quack medicine by means of a careful supervision of all communications and, as regards the public, by contributing to conferences and lectures and to radio and film propaganda; as regards the medical body, by contributing to conferences for doctors aiming to keep them informed on little known remedies. The "New Therapeutics Commission," lately established in the academy, will also be rendered more efficient. This commission will have to reply to all queries from doctors concerning remedies. These replies will remain confidential. Besides this direct action, the academy will pursue a lengthy work, which consists in preparing, in collaboration with the Ministries of Justice and for Public Health, special laws on this subject. In the meantime the Consultative Commission to the Ministry for Public Health has been created.

Precise Endobronchial Penicillin Therapy of Lung Abscesses

Penicillin, intramuscularly administered, has not given satisfactory results in abscesses of the lung and above all does not take the place of surgical intervention. Charles Mattei M. Recordier, M. Tristani, H. Metras and A. Barbe of Marseilles have succeeded in treating clearly delimited abscesses of the lung with their method of endobronchial instillations of penicillin.

The technic, simple and always without bronchoscopy, is as follows: After a good local anesthesia with pontocaine, the authors direct, under screen control, a special india rubber sound of various curvatures, opaque to rays, in the abscess region. Once the sound is placed, the patient is extended in a position sloping downward with respect to the part to be subjected to instillation; then a syringe filled with 50,000 or 100,000 Oxford units diluted respectively with 10 or 20 cc. of serum, kept tepid at about 25 degrees, is connected to it. Those instillations are repeated every other day except in the presence of abundant hemoptysis. Treatment can be effective with four instillations of 50,000 or 100,000 Oxford units, but as a rule eight to twelve are necessary. By means of iodized oil the authors verify the precision of the instillations at the beginning of the treatment and after its completion. They emphasize that neither the age of the abscess nor the doses employed are important, but that the zonal location, determining the route of endobronchial access, is the important factor. The authors have set forth before the National Academy of Medicine and the Medical Society of the Paris Hospitals their complete clinical and radiologic observations in 81 cases of pulmonary abscesses thus treated with great success, always without bronchoscopy and with absence of danger (2,320 instillations were performed without incident). At the same time they illustrated, by means of projections, the definition of the "frank" abscess, for which endobronchial penicillin therapy is to be applied. Among the 81 cases the authors have noted 50 clinical and radiologic cures, 16 cases of decided improvement with clinical cure but persistence of some x-ray signs, 5 cases of distinct improvement characterized by the disappearance of fetidness and the almost complete disappearance of sputum, extensive improvement of the general condition but persistence of the x-ray signs and 10 failures, 6 neoplasms, 2 polycystic lungs, 1 abscess with retractile cavity and 1 old seat of abscess on a pleura largely fused.

An Unpublished Manuscript of Claude Bernard

An unpublished manuscript of Claude Bernard, one of the founders of classic French medicine, who died seventy years ago, has been found among the documents and notes of the late Professor d'Arsonval. Its title is "Principles of Experimental Medicine." It is going to be published under the auspices of Dr. Delhure of Paris.

Compulsory Medical Examination of School Children

The Medical School Services are making preparations for the medical examination of all children attaining school age in October. This preventive examination, performed free of charge, takes the place of the Social Security System third examination. Half a million children will be examined, the first occasion of this sort in France.

ITALY

(From Our Regular Correspondent)

FLORENCE, June 12, 1947.

National Congress for Internal Medicine

At the first postwar national Congress for Internal Medicine, held in Florence at the same time as that for surgery, Professor Cesare Frugoni, director, Medical Clinic, University of Rome, paid tribute to the members who died during the war. A paper on tumors of the colon was presented by Professor Alessandrini in joint session with the Surgical Society. Professor Guido Izar of Siena presented a paper on modern conceptions of malaria. According to the speaker, malaria has been given the honors of the stage in a medical congress after fifty-six years of silence. The many famous Italian malariologists have died except for Professor Giuseppe Bastianelli, who is the chief of the National Institute for Malariology. Professor Izar said that a short time ago only three species of plasmodia were considered causative agents of malaria in man: Plasmodium vivax, Plasmodium malariae and Plasmodium falciparum. A fourth parasite was discovered, Plasmodium ovale, which is more benign. This parasite may rarely be encountered in Europe and is of less importance than in the American and African countries. Formerly it was axiomatic that the parasite transmitted by the bite of the mosquito may invade the red blood corpuscles to start the asexual cycle and that the plasmodium may survive and reproduce itself only in the red elements. Today we know that the sporozoites do not penetrate directly the red elements but that they may first invade some tissue cells, especially those of the reticuloendothelial system, starting the cycle of asexual reproduction and giving place to the merozoites, which may attack the red elements of the blood. This modern concept is important for prophylaxis and treatment of malaria because the sporozoites, the elements which may derive from them in the lymph channels and the elements of the so-called histotropic phase of the monogonic asexual cycle are refractory to the known antimalarial preparations. This fact explains the fallacy of chemical prophylaxis whether it is carried out with quinine derivatives, acridine derivatives or sulfonamides. In considering the second phase of the development of the malaria parasites following the disappearance of fever, the speaker stated that the parasites have not disappeared from the vertebrate host, for after a variable length of time (sometimes after a decade) fever may reappear and the clinical picture of malaria may be repeated. Professor Ascoli used the term "focal phase" for this period, emphasizing that the parasites have their seat in foci. Professor Izar concludes that one may accept the hypothesis that during these long latent periods the parasites may be lodged in the internal organs but not in the red blood corpuscles, although in tissue cells.

In discussing prophylaxis of the malarial infection—which must be distinguished from malarial disease—the speaker emphasized that up to now prophylaxis has been instituted on mistaken bases for which little proof has been furnished. Today we are in a position only to carry out a symptomatologic prophylaxis with regard to the course of malaria in delaying and in reducing the clinical picture by means of chemical prophylaxis. Many of those in attendance participated in the discussion.

Professors Cesare Frugeni and Coppo of Rome reported on the third subject, "epidemic hepatitis." During World War I episodes were described which today would most likely be classified as infections of epidemic hepatitis, but only the experiences in the recent war have established beyond doubt that epidemic hepatitis cannot be caused by bacteria or by any known toxins. Epidemic hepatitis may at present be considered an infectious disease caused by an ultravirus with an initial general infection which later may be localized in the liver, spontaneously contagious from man to man by direct contact with drops of saliva and of nasopharyngeal mucus. Sometimes it may spread among a group of persons by pollution of food or water with feces or urine of patients. It may also be transmitted artificially from man to man. Rise of temperature may sometimes occur unexpectedly after an incubation period of one month's duration on an average. There follows a second phase with the disappearance of fever and the occurrence of hepatocellular icterus of variable intensity, which, however, may not be obligatory. Among the symptoms are disturbances of digestion with constipation and increase in volume and in firmness of the liver; splenomegaly may be frequent. Leukopenia with lymphomonocytosis may be present. The so-called reaction of hepatic serolability may precociously be positive, while heterophil agglutination may always give negative results. The course as well as the clinical picture may be atypical.

Prognosis generally is favorable, and definite recovery with functional and anatomic restitutio ad integrum of the liver may occur in 99 per cent of the cases. Complications may occur. Rarely grave symptoms may develop which may be reversible but from which death may result with a picture of acute hepatic atrophy.

In prophylaxis, gamma globulin injections proved effective during the incubation period. The administration of convalescent serum may be associated with the risk of transmitting the same hepatitis in the form of the so-called icterus of homologous serum or posttransfusion hepatitis.

Nicotinic acid and liver extract may be useful for treatment. The patient should be placed on a liver protective diet. In cases with a protracted course and with symptoms of dangerous insufficiency of the liver, highly satisfactory results may be obtained with the administration of large quantities (10 to 12 liters in three days) of isotonic glucose solution by means of a duodenal tube. Other forms of hepatitis have been described as related to epidemic hepatitis, with which they have features in common; e. g. the considerable number of cases of hepatitis with jaundice a hundred days after transfusion of blood, serum or plasma. Cases of hepatitis after vaccination against yellow fever as after the administration of antitoxic serums represent only particular aspects of posttransfusion hepatitis, because the blood of the convalescent may be the vector of the icterogenic virus. Episodes of icterus accidentally transmitted from one person to another by means of an unsatisfactorily sterilized syringe have in addition been reported.

Professor Coppo and Professor Frugoni commented on the remarks of the discussers. With reference to the benign character of epidemic hepatitis which was questioned by some of the discussers, the speakers held that in spite of some malignant episodes the disease usually has a benign character and recovery without sequels occurs in almost every case.

The congress selected Rome for the next annual meeting and, as subjects for papers, (1) the mediastinal syndrome (in cooperation with the Italian Society of Surgery), speaker from the medical point of view, Professor Condorelli of the University of Catania; (2) encephalitis, speaker, Professor Greppi of Florence; (3) medical treatment of thyrosis, speaker, Professor Bastai of Padua.

Pasteur Celebration

Italy participated in the celebration of the fiftieth anniversary of the death of Pasteur in Paris through a delegation of scientists under the chairmanship of Professor Marotta, director general of the Superior Institute of Health. Professor Alberti reviewed the work of Professor Giuseppe Sanarelli and Professor Alessandro Salimbeni, the Italian pupils of Pasteur, the first of whom died shortly before the recent war and the second during it. The work of Professor Sanarelli is so extensive that it cannot be summarized briefly. The activities of Professor Salimbeni are closely associated with the practice of vaccination; he worked with Roux and Metchnikoff on cholera, with Calmette on plague, with Marchoux on yellow fever and spirilla and on antityphus vaccination with Widal. Other Italian pupils of Pasteur are Professors Malfitano and Stassano, while Professors Camillo Ninni and Federigo Netti have worked at the Pasteur Institute in Paris.

Rheumatism

Little work has been done on rheumatism within the field of internal medicine in Spain. Except for the first contributions of Professor Gregorio Marañon's school, which were stopped by the civil war, of Professor J. Cuatrecasas (now in exile) and of Dr. M. Bastos (now without a department of his own to work in, owing to political reasons), it may be said that, up to a few years ago, there was no complete rheumatologic work done in Spain. But now it has been taken up by Professor A. Pedro y Pons, professor of internal medicine at the Barcelona Faculty, and his disciple Dr. P. Barceló Torrent, head of the rheumatism clinic of that body, the first rheumatism department to be set up in Spain.

Dr. P. Barceló, who had already published a monograph in 1941 entitled Reumatismos articulares cronicos (Salvat, Barcelona), gave us another in 1945 with the title Reumatismos vertebrales (Salvat, Barcelona) in which he expounded with great clearness his personal views on rheumatic pathology. In the latter book he paid careful attention to the clinical study of the small vertebral articulations; but now he has written, jointly with the head of the radiology department of the Barcelona Faculty, Dr. J. M. Vilaseca Sabater, a further monograph devoted exclusively to this subject (Patologia de las pequeñas articulaciones inter-vertebrales: Clínica y Radiología, Salvat, 1946). Dr. Vilaseca's contribution is a model of exposition. Since the first papers of Dittmar (1931), didactic works on this subject have been very scarce. The chapters devoted to the anatomy, the x-ray observations and the pathologic systematizing of these disorders, to the uncovertebral articulations, the costovertebral and the costotransverse ones, constitute a good personal contribution.

We have to stress the greatness of the task achieved in this field at the present time by Professor Pedro y Pons's school, which led up to the recent foundation of the journal *Revista Española de Reumatismo y Enfermedades osteoarticulares* under the sponsorship of Professors Pedro y Pons, G. Marañon, J. Gibert Queralto, J. M. Vilardell, the anatomopathologist, J. Sánchez Lucas, a disciple of Aschoff, and M. Bastos Ansart. The assistant editors are Drs. P. Barcelo and J. M. Vilaseca. This review has already published comprehensive papers on senile vertebral kyphosis and osteoporosis by Dr. Pedro y Pons and the anatomic morphology of rheumatic lesions by Dr. Sánchez Lucas and has just published a paper by Dr. M. Bastos and his son Dr. Bastos Mora on an undescribed disorder of the Tarsian skeleton, a process marked by a reactional inflammation round a healthy bone fragment (which, at first, may have been an ossification nucleus detached from the astragalus or a necrotic inflammation of the spongy bone) followed by an expelling reaction in the subjacent bone. The journal is publishing two complementary monographs on ancylopoietic spondyloarthritis (October 1945) and the intervertebral disk, written jointly by some of the best specialists on rheumatism of the Barcelona school. The former contains detailed studies of 153 cases seen at the rheumatism clinic and of others seen privately by some of the writers, and in it the pathogenic concepts developed by Barcelo stand out. In the latter may be mentioned the chapter by Sánchez Lucas on the anatomopathology of the disk, the one by Bastos on the mechanopathology of the spine and the disks, in which he gives us the full fruits of his rich experience and sifted judgment; the one on radiology by Drs. Vilaseca and Vilar Bonet; that by Pedro y Pons and Barcelo on the isolated discal degeneration syndrome and a good revision of concepts by Professor Gibert Queralto on the disk in rheumatic spondylopathies.

All this work has been done by the rheumatologic school of Barcelona, where the best work on the subject is now being done in Spain. And it is to be expected that these enthusiastic collaborators will garner gratifying fruits for Spanish rheumatology, which had given but few signs of life since the days of Marañon and Cuatrecasas's early essays. Now the fight against rheumatism will be energetically undertaken and pursued with state aid, and its direction has been entrusted to other schools, which have done, notwithstanding, less valuable work than that of these men in Barcelona.

Endocarditis

Professor A. Pedro y Pons's school has also carried out some excellent investigations in the field of brucellosis, viz. "Exanthematic Mediterranean Fever," by Pedro y Pons; "Leptospirosis," by P. Farreras Valenti; "Acute Glomerulonephritis" and "Werloff's disease," by the same writer, a studious and intelligent assistant professor in the same department; "Weil's Disease," by J. Gibert Queralto, and "Nephritic Forms of Endocarditis Lenta" by Pedro y Pons.

Speaking of endocarditis, under the direction of Dr. L. Trias de Bes, the director of the Infectious Diseases Hospital at Barcelona, systematic, clinical and experimental investigative work is being carried out which is to be reported at the Spanish Cardiology Congress to be held in Barcelona next December. L. Trias de Bes, with the help of Drs. A. Foz, J. Gras Riera, L. Borras and F. Ballesta, is now examining this problem in a broad manner and his preliminary communications lead us to expect ample results of great interest. Trias de Bes has described a type of bacteremic endocarditis lenta with a positive blood culture, an almost normal plasmatic syndrome, a short clinical course and well defined features, responding well therapeutically to the indicated antibiotics; and another opposite type the blood culture of which is repeatedly negative, with an intense plasmatic syndrome, a lengthy evolution with intermittent remissions and a fatal ending, resisting all antibiotics and chemotherapeutic preparations. The plasmatic syndrome which the authors point to as a differential facet is characterized by an increase of total proteins, the inversion of the albumin-globulin quotient (which becomes almost normal during the remission phases), high Weltman reaction values, maximum flocculations in Takata's reaction and early and accentuated formaldehyde and lacto jellifications of the serum. This work of Trias de Bes and his fellow investigators, some of whom also work with Professor Pedro y Pons, has enabled them to differentiate between two types of endocarditis lenta with far different prognoses and treatments, and the data furnished are the first instalments of their interesting report. One of their advance communications has appeared in the review *Medicina Clinica,* which has just published practically the whole of the papers written in Catalonia and a large part of Spain. It is directed by Dr. Pedro y Pons, with Dr. P. Farreras Valenti as editor in chief, and may be considered the best journal published in our country, being certainly the one with the largest circulation.

A New Pregnancy Test

A new pregnancy test in which the male toad is the reacting animal has been proposed by Dr. C. Galli-Mainini (*Sem. méd.* **54:**337 [March] 1947). The technic is simple: Ten cc. of a morning urine specimen is injected subcutaneously in the toad Bufo arenarum Hensel. After a period of two or three hours a drop of the toad's urine is obtained by means of a pipet inserted in the cloaca and is placed under the microscope. The positivity or negativity of the reaction is indicated by the presence or absence of spermatozoa in the toad's urine.

In 1929 Houssay and Lascano-Gonzalez observed that implantation of the anterior hypophysial lobe in the toad released the spermatozoa in the seminal tubes. De Robertis, Burgos and Breyter (1945) found that the Sertoli cells become swollen and vacuolized and release the spermatozoa, which pass out into the kidneys. Galli-Mainini observed that chorionic gonadotropin releases the spermatozoa, which are then easily found in the toad's urine.

As stated, the response is observed in two to three hours. Spermatozoa can be easily observed with a low power lens and without staining. Positive results were obtained only with the urine of pregnant women. Of the 485 positive reactions, 177 were made with a simultaneous Friedman test; the results coincided in 168; there were only 5 positive in the toad and only 3 in the rabbit. Of all the urines from pregnant women tested 92 per cent were positive, but the percentage is higher for the urine of the first months of pregnancy. None of the sexual or adrenal hormones or substances provoke the release of the spermatozoa. It has been obtained in some cases with rat hypophysis. The urine of patients with chorionepithelioma or an ectopic pregnancy gave a positive test. A higher percentage of positive tests were obtained with urine than with serum.

This new test has the advantage of being simple, rapid, specific and economical, as the urine and the microscopic examination do not need previous preparation and the toads need no special care; also the same animal can be used repeatedly.

BRAZIL

São Paulo, June 24, 1947.

Treatment of Tuberculous Meningitis with Streptomycin

Drs. Mario Mursa, João Batista dos Reis and J. Renato Woiski published recently the first report in Brazilian medical literature of a case of tuberculous meningitis in a child aged 5 years successfully treated with streptomycin. The Koch bacillus was present in the cerebrospinal fluid, and inoculation into guinea pigs was positive. Treatment was begun eight days after the onset of the meningeal signs and it lasted seventy-one days, the total dose of streptomycin given being 44,600,000 units (42,650,000 intramuscularly and 1,950,000 intrathecally, by means of lumbar and cisternal punctures). Promin was given in association with streptomycin in the final days of treatment. Drs. Mursa, Reis and Woiski believe that the results were due to streptomycin alone, which, since therapy was started, definitely improved the course of the disease. Forty days after treatment was discontinued the patient behaved normally, with no neurologic sequelae. Repeated tests of cerebrospinal fluid denoted progressive improvement, and at the end there was only lymphocytic pleocytosis (71 cells per cubic millimeter), increase of the protein content and a thin fibrinous reticulum. In spite of these good results they cannot affirm a complete recovery because the time of observation is still too short to allow a definite estimation.

Leukotomy in Treatment of Epilepsy

Soon after the cerebral leukotomy of Egas Moniz, Freeman and Watts was introduced in psychiatry as a method of treatment its application was extended to epilepsy with not very encouraging results. Dr. Mário Yahn of the Hospital de Juquery, São Paulo, chose 6 chronic epileptic patients on whom to study the effects of frontal and parietal leukotomy on the disease and secondary deviations of behavior. One patient with psychopathic personality, misconduct and hysterical and epileptic fits recovered fully after the operation. Of 2 other patients with infantile encephalopathy, hemiplegia and deviations of behavior, 1 greatly improved as to the rate of seizures, without mental changes. In the other the number of seizures was later reduced.

Of 3 other patients with essential epilepsy with deviations of behavior, 2 showed good results, and the third showed signs of aggravation. The mental state of 1 patient was improved.

Dr. Mário Yahn believes that the verified improvements do not result directly from the sectioned pathways but from a new postoperative integration. Leukotomy cannot yet be used as a routine method of treatment for epilepsy. Only in chronic and very serious cases with frequent seizures and misconduct in which shock therapy has failed should cerebral leukotomy be employed.

Cyst of the Choledochus

Dr. Erasto Gartner, professor of the Faculdade de Medicina of Curitiba, Parana, recently reported a case of cystic dilatation of the choledochus in a 14 year old patient in whom surgical exploration by a right lumbotomy showed a retroperitoneal tumor. After puncture of the cyst, from which 1,500 cc. of bile was taken, and a large incision made on its posterior wall, it was possible to observe the proximal and distal holes of the channel, resembling aneurismal sacks. The reconstruction was made by the Matas technic. The suture was made over a plummet, which was left loose in the manner of Pierre Duval, and the patient was completely cured without postoperative incidents. It is the first choledochus reconstruction made in this way. The process was called "choledochorraphy" in honor of Rudolph Matas of New Orleans. On consulting the international literature Dr. Gartner found that 183 cases have been reported.

Correspondence

CORONARY DISEASE

To the Editor:—Dr. Falk's paper on coronary disease (The Journal, June 7, p. 491) not only repeats the ancient legend that blood cholesterol is independent of dietary cholesterol intake but specifically recommends junket and eggs as daily dietary ingredients for patients with coronary disease. Falk seems not to have noted the fall in blood cholesterol reported by Kempner in 79 patients on a rice diet (the average fall was from 243 to 186 mg. per hundred cubic centimeters. *Bull. New York Acad. Med.* 22:361 [July] 1946) or the consistent slight rise in blood cholesterol noted in normal women fed four egg yolks daily (Okey, Ruth, and Stewart, Dorothy. *J. Biol. Chem.* 99:717 [Feb.] 1933).

Granting that blood cholesterol is rather stable, rising and falling slowly when diets rich in cholesterol and calories are administered or discontinued, and that going without favorite foods is to many a "fate worse than death," it must be conceded that atheromas form more slowly in races on a low cholesterol intake, that atheromas occur in fatal form precociously in those with high blood cholesterol (xanthomatosis, diabetes mellitus) and that high blood cholesterols are the rule in those who have coronary disease before 50 (Lerman, J., and White, P. D.: *J. Clin. Investigation* 25:914 [Nov.] 1946). It is also certain that ingestion of egg yolk, butter and cream furnishes calories and cholesterol in concentrated form. If a patient is concerned about duration of life, if he feels some obligation to his dependents, it would seem to be proper for him to reduce his weight to the ideal for his body build at age 20 and to avoid the substances noted as regular items of diet. No doctor should prescribe them for him.

Arguments against this view are summarized by Peters (Quantitative Clinical Chemistry, vol. 1:534-1536, Baltimore, Williams & Wilkins, 1946). These arguments are precisely the same as those which were used to destroy the theory of Villemin that tuberculosis was an infection. Not all the people heavily exposed to tuberculosis or cholesterol die of the disease; the lesions in experimental animals differ in some respects from those in man. On the other hand, no one who is not exposed to tuberculosis dies of that disease, and no one with a blood cholesterol under 150 mg. per hundred cubic centimeters is likely to die of coronary disease. Dogs, rabbits and chickens all get atheroma when the blood cholesterol is kept above 250 mg. per hundred cubic centimeters, and the higher the level the more rapidly do severe lesions develop. These lesions all resemble human atherosclerosis far more closely than Villemin's guinea pig tuberculosis resembled human phthisis.

We read today that millions are to be spent for research on heart disease, and we hope this may lead to reduction of blood cholesterol without dietary restriction. More men's lives would be saved by this than by a specific cure for cancer. Meantime, geographic pathology, clinical observation and experimental pathology have shown how atherosclerosis can be prevented, or even reversed, by dietary restriction alone. Whether this is worth while for those who live to eat is beside the point; doctors must tell their patients how to eat in order to prolong their lives.

Hypertensive people (who have five times the incidence of coronary disease of the normotensive), those with bad family records of coronary disease and those who are obese or have high blood cholesterols should be clearly informed of the advantages of a low calory diet, low in egg yolk, butter and cream. They might even be informed of the fact that on a vegetarian reducing regimen life not only will seem longer but statistically it will be longer.

William Dock, M.D., Brooklyn.

OBESITY

To the Editor:—In his paper on "Psychic Factors in the Development and Treatment of Obesity" (The Journal, February 8, p. 369) Dr. Freed laid particular stress on the etiologic importance of psychosomatic factors in the pathogenesis of obesity. In his communication April 5 (p. 1032) Dr. Freyhan emphasized the constitutional aspects. Both these factors play an essential role. After all, every case of obesity is brought about by "overfeeding," either absolutely or relatively. However, we would underestimate the complexity of the question if we believed that these two factors are sufficient to solve completely the problem of obesity (or likewise of emaciation). Even if factors such as temper, basal metabolism, alimentary extravagance, the specific dynamic effect of food and caloric consumption during and after physical exertion are properly taken into account, we are left with a number of patients whose tendency toward obesity remains unexplained. And, strangely, this is particularly true of the extreme types of obesity such as are sometimes found with pituitary tumors, tumors in the occipital fossa compressing the aqueductus cerebri and so on. Localized obesity, e. g. lipomatosis of the lower extremities in hyperthyroidism represents a special problem. Here a localized failure to combust fats in spite of a generally increased oxidation in the organism plays the decisive role (Zondek, H., and Loewy, A.: *Ztschr. f. klin. Med.* 95:282 [Nov.] 1922). This localized obesity is certainly difficult to interpret from the psychosomatic point of view. I should like to mention that form of obesity which I described about twenty years ago and designated as "water-salt obesity" (*Deutsche med. Wchnschr.* 31:1267 [July 31] 1925). In such cases water and salt retention accompanied by a tendency toward fat deposition in the tissues appears to be the essential etiologic factor. I am unaware of the incidence of this type of obesity in the United States, but in the Middle East (e. g. Palestine, Iraq, Syria, Egypt) it is widespread. This type of obesity does not react to treatment on the so-called glandular basis or to caloric restriction or to psychic approach but only to restriction of water and salt intake and to mercurial diuretics and other dehydrating measures.

Herman Zondek, Jerusalem.

MEDICAL EDUCATION IN ITALY

To the Editor: In an article by Dr. W. C. Davison (The Journal, April 6, p. 921) the condition of Italian medical education before and after the second world war was criticized. I feel it my duty to clarify the facts.

The inevitable consequences of a long war deprived us of valuable men, material and buildings. At present, two years after the end of the war, Italian universities are in financial difficulties, with a greatly increased number of students. The expenses which have been met already and which are necessary to reconstruct the damaged buildings are absolutely enormous. Replacement of equipment (instruments, reagents, animals, books) is another heavy problem. It is feared that some old universities will have to be closed for lack of funds. However, medical scientific activities have never ceased. In October 1946 the first postwar national medical meetings took place in Florence and were remarkably successful.

The results achieved in Italy in the scientific medical field are worthy of general recognition. For example, hematology is a branch of pathology which has always appealed to our research workers. The discovery of acute erythremia, the extensive study of the acute erythremic condition, of Cooley's and related syndromes and of their relationships to constitutional hyperhemolysis and hemolytic icterus with increased globular resistance, the study of bone marrow in surviving explants, the neoplastic interpretation of acute and chronic leukemias and the establishment of different characters among various types of acute monocytic leukemias represent some of the work recently done in this field.

Italian doctors are skilful in controlling the diffusion of pulmonary tuberculosis caused by the war and malnutrition. The method of so-called endocavitary aspiration for the treatment of pulmonary cavities, some types of apicoaxillary thoracoplasty and special types of extrapleural pneumothorax are recent discoveries of Italian phthisiology. Experimental and clinical tests with lipotropic agents have given excellent results in the relationship between the function of the adrenals and lipotropic action, pregnancy and hepatic steatosis due to deficiency of labile methyl groups and the lipotropic effect and functional efficiency of the liver in the hepatomegalic diabetes of the young.

The new views on an intracellular cycle of the malarial parasite (histotropic phase) have been repeatedly confirmed by the increased observations due to the diffusion of malaria as a consequence of the destruction of antimalaria wards during the war. Prominent in the field of allergic diseases in our country are the problems of histamine and artificial antihistaminic drugs.

The discovery in Italy of electric shock was an important contribution to scientific advancement in the field of psychiatry. The identification of infantile acrodynia as a syndrome due to deficiency of pyridoxine is one of our most important contributions in this branch.

A serious problem to be solved is that of Italian medical literature. Efforts must be made to have our work better known abroad.

I hope I have made clear that Italian doctors can be favorably compared to those of other European countries.

I thank the Editor for the opportunity offered me to express my opinion on the subject.

Cesare Frugoni, M.D., Rome, Italy
Head of the Department of Internal Medicine,
University of Rome; President, Italian Society
for Internal Medicine.

STREPTOMYCIN THERAPY AND EOSINOPHILIA

To the Editor:—The observation of eosinophilia in patients with tuberculosis under therapy with streptomycin in the absence of eruption is reported by Farrington and his associates in The Journal, June 21, page 682. In 9 of 14 subjects the eosinophilia first appeared during the second and third months of therapy and was not associated with symptoms or signs suggesting sensitivity to the drug. A similar phenomenon has been observed in the therapy of leprosy with streptomycin (Faget and Erickson: Use of Streptomycin in the Treatment of Leprosy: A Preliminary Report, read before the Antibiotic Study Section, U. S. Public Health Service, Washington, D. C., Feb. 1, 1947). These authors found that the peak of eosinophilia occurred during the twelfth week of treatment, following which the eosinophil count gradually dropped. Only one patient had a conspicuous skin eruption, though 3 other patients had milder attacks of dermatitis. Eosinophilia was observed in all 10 patients treated. Erickson informed me that they have observed eosinophilia in patients with leprosy for as long as five months after discontinuance of streptomycin therapy, and that all patients had normal counts prior to the treatment.

The fact that the eosinophilia appeared in some instances to rise to a peak and then to recede while therapy was continued suggests a definite effect on the infection. In experiments in which purified lipid fractions of tubercle bacilli were injected into human beings (Harrell, G. T.: *J. Clin. Investigation* **23:**943 [Nov.] 1944) the cellular reaction in tissue removed at biopsy revealed considerable numbers of eosinophils as well as polymorphonuclear neutrophils and epithelioid cells. This finding suggests a possible mechanism for the eosinophilia. If streptomycin inhibits the growth of acid fast organisms so that the immune response of the body destroys moderate numbers of Mycobacteria, the gradual destruction of the cell body would liberate these firmly bound lipids. The observation that the phosphatide and wax are biologically active, as is shown by the production of chronic wheals, would suggest that a firmly bound portion of the molecule, probably a polysaccharide, is released in the tissue and elicits the eosinophil response.

If the development of eosinophilia can be correlated with a subsequent favorable clinical response, a simple means of estimating the efficacy of streptomycin therapy will be available. It is conceivable that the absence of an eosinophil response in the second month of therapy might be indicative of the development of a drug fast strain, which could then be investigated by cultural methods. The rise and fall of reticulocytes in patients with pernicious anemia under therapy with liver is well known and represents an analogous measure of the effectiveness of therapy through a hematologic response.

George T. Harrell, M.D., Winston-Salem, N. C.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

BOARDS OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in The Journal July 26, page 1121.

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I and II.* Various centers, Sept. 15-17. *Part III.* Durham, Oct. 21-23. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: Part II. *Oral.* Cleveland, Oct. 5-11. Sec., Dr. P. M. Wood, 745 Fifth Ave., New York 22.

American Board of Dermatology and Syphilology: *Part I. Oral.* Chicago, Oct. 24-26. Final date for filing application is Aug. 1. *Part II. Written.* Various centers, Sept. 15. Sec., Dr. G. M. Lewis, 66 E. 66th St., New York 21.

American Board of Internal Medicine: *Oral.* Chicago, Oct. 8-10. Asst. Sec., Dr. W. A. Werrell, 1 West Main St., Madison 3.

American Board of Neurological Surgery: *Oral.* Chicago, May or June. Final date for filing application is Feb. 1. Sec., Dr. W. J. German, 310 Cedar St., New Haven, Conn.

American Board of Obstetrics and Gynecology: *Part I. Written.* Various Centers, Feb. 6. Final date for filing application is Nov. 1. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh 6.

American Board of Ophthalmology: Chicago, October 6-12. Sec., Dr. S. Judd Beach, 704 Congress St., Portland, Me.

American Board of Orthopaedic Surgery: Part II. Chicago, Jan. 22-23. Final date for filing application is Sept. 15. Sec., Col. F. M. McKeever, 1136 W. Sixth St., Los Angeles 14.

American Board of Otolaryngology: Chicago, Oct. 7-11. Sec., Dr. D. M. Lierle, University Hospitals, Iowa City, Ia.

American Board of Pathology: Chicago, Oct. 24-25. Final date for filing application is Sept. 15. Sec., Dr. Robert A. Moore, Euclid Ave. and Kingshighway, St. Louis 10.

American Board of Pediatrics: Dallas, Dec. 5-7. Philadelphia, Jan. 9-11. Sec., Dr. Lee F. Hill, 718 Royal Union Bldg., Des Moines 9.

American Board of Plastic Surgery: Examinations are given in April and November of each year in the home town of applicants. Applications should be sent to Sec., Dr. Louis T. Byars, 508 N. Grand Blvd., St. Louis.

American Board of Psychiatry and Neurology: *Oral.* New York, December. Final date for filing application is Sept. 15. Sec., Dr. Francis J. Braceland, 102-110 Second Ave., S. W., Rochester, Minn.

American Board of Radiology: *Oral.* Boston, Nov. 26-30. Final date for filing application is Aug. 1. Sec., Dr. B. R. Kirklin, 102-110 Second Avenue, S. W., Rochester, Minn.

American Board of Urology: Chicago, February. Final date for filing application is Nov. 1. Sec., Dr. Harry Culver, 1409 Willow St., Minneapolis 4.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Coroners: Validity of Statute Relating to Jurisdiction.—The plaintiff filed an action for a writ of mandamus to direct the county coroner to change his verdict in a particular case from "suicide" to "accidental death." From a judgment for the defendant, the plaintiff appealed to the court of appeals of Ohio, Cuyahoga County.

The plaintiff's husband was admitted to a hospital on Nov. 8, 1945, where he underwent surgical treatment. After the operation he was placed in a room on the fourth floor of the hospital and during the period between the 8th and 11th, and until shortly before his death, he was given several dosages of phenobarbital as part of the essential medical treatment prescribed for him. About 1:40 p. m. on Nov. 11, 1945 the body of the plaintiff's husband was found on the ground outside the hospital building, the exact manner and means by which the body got there being unknown. The coroner made a finding that the immediate cause of death was "multiple fractured ribs, internal injuries, suicide, jump from window," but the plaintiff alleges that when the coroner made this decision he was not in possession of all the facts and information relating to the death of the deceased, especially such as relate to the influence of the administration of phenobarbital as a sedative. She contends that the graded cumulative effect of the administration of phenobarbital, coupled with postoperative shock, was sufficient to cause deceased's mental processes to become impaired and that the coroner would and should have rendered a different decision as to the cause and manner of death had he been in possession of all the facts relating thereto. The coroner incorporated in his verdict, and in the death certificate filed with the registrar of vital statistics in Cleveland, his decision of suicide and the plaintiff urges that the decision is in part erroneous and that the verdict of the coroner should have been that deceased came to his death by "accidental" means.

Prior to 1945 it was thought that the jurisdiction of a coroner, under statutes existing at that time, was confined to cases where there was a "suspicion of death" by criminal means. In 1945 certain sections of the coroner act were amended so that the jurisdiction and authority of the coroner was, for the first time in the history of the state, enlarged to cover cases involving civil liability. For instance, section 2855-5 provides for cases where "any person shall die as a result of criminal or other violent means, or by casualty, or by suicide" and section 2855-7 contains the words "whether by violence to self or from any other person or persons." Section 2855-16, provides: "The cause of death, the manner and mode in which the death occurred, as delivered by the coroner and incorporated in the coroner's verdict and incorporated in the death certificate filed with the registrar of vital statistics, shall be the legally accepted manner and mode in which the death occurred and the legally accepted cause of death, unless the court of common pleas of the county in which the death occurred, after hearing, directs the coroner to change his decision as to the cause, mode and manner of death." From the plain language of this section, said the court of appeals, we conclude that the legislature intended to enlarge the jurisdiction of the coroner to cases of death where civil rights and liabilities may be involved.

It is urged by the defendant, however, that the language of section 2855-16 providing for a hearing by the court of common pleas is so incomplete, vague, indefinite and uncertain that it is impossible to determine with any reasonable degree of certainty what the legislature intended. It is then argued that, since there is no other provision to supplement section 2855-16, the deficiency is such as to render it impossible of execution and therefore void.

It is clear, said the court, that the legislature, by enacting section 2855-16, intended to clothe the court of common pleas with jurisdiction to direct the coroner to change his decision as to the cause, mode and manner of death if, in the judgment of the court, the coroner's verdict is not justified by the evidence. The serious question, however, is how, or in what manner, this legislative intent is to be effectuated under the statute as written. It will be noted that, under this and the other new sections of the General Code, there is no method prescribed as to the manner in which the decision of the coroner shall be brought before the common pleas court. There are no provisions describing the person or persons who shall or may be made parties to such action, and the section is wholly silent as to how such parties shall be brought before the court for adjudication. Furthermore there does not appear to be any other provision of law conferring jurisdiction on the court of common pleas to decide such questions either in original or review proceedings and no other statutory provision setting forth the nature of such proceeding. Continuing, the court said that there is another important question in this case, namely, whether or not there is a grant of judicial power to the coroner, a ministerial officer, to make a finding in an ex parte proceeding affecting constitutional rights in civil matters. While we are not concerned with the wisdom or policy of the legislature, said the court, we must be concerned with the constitutional rights of any persons who may be prejudiced by an ex parte finding of a ministerial officer in a proceeding in which they are not made parties and in which they are not afforded means of becoming parties for the purpose of asserting their rights.

After discussing the new provisions of the coroner's statute and considering prior Ohio cases and cases from other jurisdictions, the court concluded that the new sections were an attempt by the legislature to vest the coroner with judicial power in civil matters between private parties which is repugnant to the Ohio Constitution vesting full judicial powers in the court; that the legislature attempted to authorize the coroner to make "legally accepted findings" having the power of judicial decisions affecting civil rights in ex parte proceedings, without making adequate provisions for defining means for persons adversely affected thereby to be made parties or become parties for the purpose of asserting and protecting their rights; that the legislature attempted to vest the court of common pleas with the power to direct the coroner to change his finding in a civil matter so that it will thereafter have the force of a judicial decision without providing the method or means by which such jurisdiction shall be exercised and without providing some mode or method which will guarantee the parties their constitutional rights to have their day in court. Such a statute, said the court, is inoperative and void for uncertainty and indefiniteness, deprives a party of his fundamental rights and is violative of both the Ohio and the federal constitutions. Accordingly the judgment of the trial court in favor of the defendant was affirmed.—*State v. Gerber, Coroner, 70 N. E. (2d) 111 (Ohio, 1946).*

Medical Motion Pictures

FILM REVIEW

The Control of Voluntary Muscles (Some Principles of Kinesiology). Directed by Frederic T. Jung, Ph.D., M.D., and William H. Lazear, D.D.S. Produced in 1943 by Northwestern University Medical School. Photography by Mervin W. LaRue. 16 mm., color, silent, 575 feet (two reels). Showing time twenty-three minutes. Procurable by rental, $2, or by sale from Audio-Visual Medical Education Department, Northwestern University Medical School, 303 East Chicago Avenue, Chicago 11.

This film clearly portrays muscle action in the human body. Primary attention is given to the muscles ordinarily used in large muscle activities and those which are most often involved in therapeutic exercise. The position, shape and attachment of muscles are first illustrated by drawings and their action then demonstrated by a living model.

The film is intended as a visual teaching aid for courses in kinesiology as provided for students in physical education and physical therapy. The purpose of the film is not to provide a general overall view of the subject but rather to present some aspects of kinesiology from the standpoint of voluntary muscle control.

While it will prove most useful for students in physical education and physical therapy, it may also be of real value in stimulating interest in general courses in anatomy. The color photography is excellent.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American J. Obstetrics and Gynecology, St. Louis

53:721-900 (May) 1947. Partial Index

Presidential Address: Individualism. J. H. Moore.—p. 721.
Menorrhagia Associated with Irregular Shedding of the Endometrium: Clinical and Experimental Study. E. G. Holmstrom and C. E. McLennan.—p. 727.
Physiologic Action of Human Chorionic Hormone: Production of Pseudopregnancy in Women by Chorionic Hormone. W. E. Brown and J. T. Bradbury.—p. 749.
*Combined Evipal and Scopolamine Analgesia and Cyclopropane Anesthesia in Obstetrics. H. E. Anderson.—p. 758.
Stress Incontinence in the Female. R. A. Reis and E. J. De Costa.—p. 776.
Constriction Ring Dystocia. L. Rudolph and C. Fields.—p. 796.
*Minimal Spinal Anesthesia in Vaginal Delivery: Analysis of 1,000 Consecutive Cases. J. A. Haugen and R. C. Benson.—p. 805.
Management of Delivery Following Stillbirth from Previous Dystocia. A. B. Hunt and R. W. DeVoe.—p. 812.
Blood Calcium: Normal Curve for Pregnancy. R. L. Newman.—p. 817.
Experience with Midpelvic Dystocia: Preliminary Report. W. C. Eller, W. F. Mengert, W. H. Andrew Jr. and R. J. Jennett.—p. 823.
Penicillin and Acute Puerperal Mastitis. C. P. Hodgkinson.—p. 834.
*A 55 Pound Solid Uterine Myoma. W. D. Beacham, J. A. Holmes, H. T. Beacham and others.—p. 839.
Leiomyofibroma of Uterus and Endometrial Carcinoma. R. S. Siddall.—p. 846.
Study of Interaction of Pregnancy and Hypertensive Disease. L. C. Chesley, J. E. Annitto and D. G. Jarvis.—p. 851.
Placental Metabolism of Vitamin C.: II. Histochemical Analysis. J. H. Holzaepfel and A. C. Barnes.—p. 864.
Spontaneous Annular Detachment of the Cervix During Labor. C. B. Ingraham and E. S. Taylor.—p. 873.
Subacute Bacterial Endocarditis During Pregnancy. M. E. Davis and R. F. Wortmann.—p. 878.

Analgesia and Anesthesia in Obstetrics.—Anderson studied 700 obstetric cases in which the combined amnesic and anesthetic action of evipal soluble given rectally, scopolamine hydrobromide given hypodermically and cyclopropane administered by inhalation was found safe and effective. Analgesia and amnesia were complete in 93 per cent of cases; in 7 per cent little or no relief of pain was experienced. The 4 stillbirths occurring in this group had no connection with the analgesia and anesthesia. Less than 7 per cent of newborn babies required artificial resuscitation. All of these survived with no further trouble after resuscitation. About 5 per cent of patients became difficult to manage while under sedation. This is an improvement over results with most barbiturate-scopolamine combinations. Cervical lacerations amounted to 4 per cent and were repaired immediately following delivery. This small incidence of laceration speaks well for the relaxing effect of evipal and scopolamine on the cervical muscle fibers. There was an increase in the proportion of perineal application of forceps in vertex presentation, especially in primigravidas, whenever analgesia and surgical anesthesia were used.

Minimal Spinal Anesthesia in Delivery.—Haugen and Benson analyze 1,000 cases delivered under "minimal dose spinal anesthesia." Metycaine 22.5 mg. (1.5 cc. of a 1.5 per cent solution) was found to be the minimal practical dose and was used in every instance. There were no instances of the usually feared side effects of spinal anesthesia in the obstetric patient. "Minimal spinal anesthesia" in this series proved to be a safe and desirable anesthetic method for operative vaginal delivery, and the results indicate that it deserves a place in the obstetrician's armamentarium for use in selected cases.

A 55 Pound Solid Uterine Myoma.—Beacham and his associates report the removal from a woman aged 59 of a solid myoma which weighed 55 pounds (25 Kg.) and measured 17 inches (43 cm.) in diameter. The patient is enjoying excellent health four years after operation.

Poliomyelitis and the Otolaryngologist. P. M. Hamilton.—p. 161.
Premedication in Tonsillectomies in Children Under Six Years Old. Margaret Noyes Kleinert.—p. 168.

Effect of Application of Nose Drops on Nasal Mucosa of Rabbits.—Ryan used two types of proprietary nose drops to determine the effect of nose drops on the nasal mucous membrane of rabbits. Each of these preparations quickly destroyed the cilia. There was no evidence of development of new cilia during the study. The epithelium was transformed into stratified squamous epithelium. The author concludes that the overuse of nose drops is harmful to the nasal mucous membrane of the rabbit. The clinical picture in rabbits was similar to that observed in human beings who had used nose drops excessively. Nose drops should not be used promiscuously.

Acute Mastoiditis Masked by Penicillin Therapy.—Barrett shows that penicillin will cure most cases of acute otitis media if given in adequate doses, the exceptions being the ones due to bacteria that are insensitive to the drug. Penicillin is effective in the phlegmonous form of acute mastoiditis. After the infection has progressed to the stage of coalescent mastoiditis the drug alone is not sufficient. The severity of the disease process is reduced, but the usual clinical symptoms and findings are often distorted. Penicillin therapy changes the clinical picture of lateral sinus phlebitis, meningitis and petrositis. Surgical intervention in addition to the administration of penicillin is necessary in the majority of such cases to effect a cure.

Splenosis.—Stobie points out that hypersplenism is being looked on as a possible cause for the destruction of all or certain elements of the blood, such as that found in thrombocytopenic purpura, where only the platelets of the blood are affected, and again in congenital hemolytic icterus, where a destruction of the erythrocytes takes place. The increased pigments in the blood and tissues from the brokendown erythyrocytes which must be excreted by the liver result in a high incidence of gallstones of the bile pigment type. That the spleen is the causative factor in these two blood diseases is proved by the improvement that follows splenectomy. True accessory spleens are found only in areas where splenic tissue developmentally arises. There is, however, another condition in which multiple pieces of splenic tissue are found attached and growing throughout the whole peritoneal cavity. This condition is splenosis which results from seeding of splenic pulp cells. The author reports the occurrence in a woman aged 23 of seeding after splenectomy for nontraumatic reasons. Surgical technic for splenectomy should be designed to remove completely all blood from the abdominal cavity, and the abdominal wall incision should also be protected from splenic blood to prevent implants. A recurrence of congenital hemolytic icterus following splenectomy may be caused by splenosis.

Obliterative Arterial Disease.—Luke reviews 25 cases recently studied in the vascular service of the Royal Victoria Hospital. Clinical and laboratory investigations and studies of specimens of leg arteries suggest that Buerger's disease is much less common than is generally believed. It is a generalized progressive disease responding only briefly to the present methods of treatment, including sympathectomy. Leg amputation is a frequent sequel. The group showing the chronic degenerative process on biopsy has a much better prognosis, owing to the slowness of the progression of the disease. These cases show a long lasting improvement following lumbar sympathectomy. The author is of the opinion that the many glowing reports previously published of the good results of sympathectomy and other treatments in Buerger's disease are incorrect, as what is being reported as Buerger's disease is not necessarily proved. A correct etiologic diagnosis of arterial occlusive disease of the legs is most difficult, especially in the young and middle aged group. Biopsy of one of the main arteries, preferably at the time of sympathectomy, will give the most information possible.

Oxygen in Air Embolism Following Artificial Pneumothorax.—Kelly and his associates report the history of a woman aged 28 in whom cerebral air embolsm followed artificial pneumothorax. Initial convulsions, coma, hemianopsia and hemianesthesia disappeared, but there was a residual left sided hemiparesis. Serial electroencephalograms showed obliteration of normal cortical activity in this instance, with a gradual return toward normal. The continuous breathing of pure oxygen for a period of nine and one-half hours, even though delayed for an interval of three days, was associated with great improvement. Present day methods of treating air embolism following artificial pneumothorax are ineffectual. The author urges the use of pure oxygen breathing over long periods to combat the unfavorable effects of cerebral air embolism immediately following the introduction of air into the circulation.

*Cold Wave Dermatitis: Report of 2 Cases. C. M. McGill and L. F. Ray.—p. 238.

Cold Wave Dermatitis.—According to McGill and Ray "cold wave" preparations contain organic, inorganic or synthetic chemicals in a strong alkaline medium which dissolve the horny sheath of the hair while it is being wound to the desired curl; then the keratolytic solution is neutralized with water or hydrogen peroxide and the hair returned to its normal consistency, "permanently" maintaining its new shape. These substances can irritate the skin of the beauty operator or the customer if contact is prolonged or frequent. In addition to being primary irritants, these materials may also develop a localized sensitivity after repeated use. Two clinically proved cases and 11 cases allegedly due to these preparations are cited.

Splenectomy in Patients Past Sixty.—Curtis and Movitz say that of 200 consecutive splenectomies done at Ohio State University Hospital there were 14 that were done on patients past 60. The good results obtained by splenectomy for congenital hemolytic icterus, primary thrombocytopenic purpura, Banti's syndrome and some of its clarified complexes indicate the procedure for these diseases in the aged. It also appears probable that splenectomy is indicated for excessive splenic thrombocytolysis or hemolysis in lymphatic leukemia. The hazards of splenectomy and those resulting from senescence are analyzed. The study reveals that no patient of the elderly group succumbed to the relatively hazardous operation of splenectomy because of senescence. Splenectomy for those who survived the operative procedure has been worth while from two points of view: The patients have improved or recovered from the splenic disease, and, secondly, their expected length of life has suffered little or no interference from the previous splenic disease.

Exchange Transfusion for Erythroblastosis Fetalis.—Platou and his associates point out that treatment of erythroblastosis fetalis has heretofore been directed primarily at the anemia only. Rh positive blood cells were used, thereby adding "fuel to the fire." Studies have shown that the fate of these Rh positive cells is early hemolysis. Some infants whose livers might tolerate the products of this hemolytic reaction did survive in spite of the added Rh positive cells. Newer knowledge regarding the pathogenesis in erythroblastosis makes liver protection the therapeutic keynote. The procedure described consists in withdrawing an infant's Rh positive cells and maternal antibody and replacing these with safe Rh negative cells and "normal" plasma. Withdrawal and replacement are done through a catheter that is inserted into the umbilical vein. Two cases of impending erythroblastosis fetalis have been treated successfully by the exsanguination transfusion technic. Two similar cases unsuccessfully treated by currently used transfusion technics are presented. The indications were multiparity, previously born erythroblastic babies, rising antibody titer, paternal homozygosity and serologic abnormality in the baby. With these indications prophylactic or early treatment is imperative. Delay has been shown to result in irreparable liver damage. Liver, iron and accessory transfusions of Rh negative cells (suspended in saline solution) are occasionally necessary to combat the aregenerative phase so frequently encountered in these cases in the first few weeks of life. Washed maternal red cells are safe for single accessory transfusion when an Rh negative donor is difficult to find.

Hypoglycemia with Hyperplasia of Islets of Langerhans.—Discussing the multiplicity of types of hypoglycemia, Agustsson and his collaborators point out that while hypoglycemia may be due to the disease of the liver and a number of endocrine glands, it most often occurs with a disturbed secretion of the pancreas. Disease of the aforementioned organs should be ruled out before focusing all attention on the pancreas. Functional pancreatic adenomas and diffuse hyperplasia of the islets of Langerhans seem to be extremely rare in infants and children. The authors report a case of severe hypoglycemia due to overactivity of the islets of Langerhans in a 4½ months old infant, with recovery following a subtotal pancreatectomy. The pathologic specimen showed hyperplasia of the islets of Langerhans. Early diagnosis and treatment are urged to avoid serious neurologic sequelae. The authors accept the first three of the four points advanced by Hartmann as criteria for the need of surgical treatment in hypoglycemia: 1. There should be proof of a persistent or a frequently recurring hypoglycemia by blood analysis. 2. It should be shown that the symptoms expected to be relieved by surgery can be relieved by dextrose administration. 3. It should be shown that the symptoms cannot be relieved by conservative measures of diet regulation.

Tracheotomy in Bulbar Poliomyelitis.—Priest and Goltz analyzed experiences with tracheotomy at the Minneapolis General Hospital during the poliomyelitis epidemic of 1946. Tracheotomy was employed cautiously. Criteria for tracheotomy were (1) respiratory distress as evidenced by recurrent cyanosis, coarse rales in the chest and laryngeal stridor; (2) excitement and unmanageability, causing the patient to resist pharyngeal aspiration strenuously; (3) stupor of a degree sufficient to make the patient oblivious to accumulation of secretion in his airway; (4) inability to cough effectively; (5) pharyngeal pooling of mucus, vocal cord paralysis or intralaryngeal hypesthesia demonstrable by laryngoscopy. Twenty-two tracheotomies were done: 7 patients lived and 15 died. It is thought that the procedure was life saving in 5 cases. Some patients probably died because the operation was performed too late.

New England Journal of Medicine, Boston

236:611-646 (April 24) 1947

*Streptomycin Treatment of Pulmonary Infections: Clinical and Bacteriologic Studies of 6 Cases. H. W. Harris, R. Murray, T. F. Paine and M. Finland.—p. 611.

Multiple Polypoid Carcinomas of Stomach, with Metastasis.—p. 634.
Adenocarcinoma of Pancreas, with Liver Metastases.—p. 637.

Streptomycin Treatment of Pulmonary Infections.—The first 3 of 6 patients in whom Harris and his associates resorted to treatment with streptomycin had severe pneumonia, which in 2 cases had failed to respond to penicillin. One of these cases, in which sulfadiazine had been used as a supplement, had a fatal outcome, but in all 3 cases there was bacteriologic evidence of improvement after streptomycin had been started. The 3 *remaining* cases represent chronic and recurrent bronchopulmonary infections in which gram negative bacilli were found in large numbers in the sputum. The streptomycin was used in these cases in an attempt to reduce the amount of cough and sputum by inhibiting or eliminating the gram negative flora. Each of these patients received a fairly long course of penicillin intramuscularly, and 2 of them also received the antibiotic by inhalation with only partial or temporary relief before streptomycin treatment was started. In 2 cases definite clinical improvement occurred after the streptomycin had been begun. In the other cases there was no improvement in spite of large doses of streptomycin intravenously and by inhalation, and death occurred. One of the causes of clinical failure appears to be the rapid development of streptomycin resistance by the infecting organisms. In 1 case drainage from a chronic suppurative otitis media stopped promptly after systemic and local streptomycin therapy.

Sensitivity to Pork Liver Extract.—Bauer and his associates report observations on 14 patients who acquired sensitivity to a pork liver extract, which was given intramuscularly to about 200 patients during this period. There were 3 varieties of clinical manifestations of sensitivity. The most frequent effect consisted of generalized itching, urticaria, edema of the face and lips, nausea and vomiting. The second type exhibited peripheral vascular collapse, including thready pulse, sweating, cyanosis, weakness and fainting. A third group of patients manifested local signs that may have been due to an Arthus type of sensitivity consisting of swelling, itching and induration without necrosis at the site of injection. The immediate symptoms of sensitivity were relieved at least in part by the injection of epinephrine. Change to an extract derived from beef liver abolished the sensitivity. Skin tests with liver extracts derived from pork, beef and lamb indicated in general greater sensitivity to extract of pork liver than to that of beef and lamb liver. It appeared that the sensitivity to liver extract represented an acquired type of species rather than one of organ specificity.

*Quinidine: A Dangerous Ally. A. D Dennison Jr.—p. 193.

Quinidine a Dangerous Ally.—Dennison points out that quinidine in overdosage can produce auriculoventricular block, extrasystoles, paroxysmal tachycardia, cardiac standstill from auricular standstill, intraventricular block and ventricular fibrillation. Contraindications to the use of quinidine include idiosyncrasy to the drug, a history of embolism, heart block, old age, congestive heart failure of long standing, great enlargement of the heart and mitral stenosis. The following are accepted indications for quinidine treatment: auricular fibrillation of less than three months' duration, paroxysmal ventricular tachycardia, episodes of auricular paroxysmal tachycardia and extrasystoles, particularly those arising in the auricle. Prophylactically it can be used in coronary thrombosis to prevent ventricular paroxysmal tachycardia and ventricular fibrillation. Occasionally it is indicated in auricular flutter.

Penicillin for Gonorrhea in the Female.—Barnes and Daly regard two considerations as fundamental in the search for the ideal form of penicillin therapy: (1) the percentage of cures, (2) the applicability of the chosen schedule to the nature of the practice and to the type of patient. Since a considerable number of patients treated by the authors are indifferent to and/or apprehensive of treatment, it has been felt imperative to achieve all therapy in one clinic visit. Sodium penicillin in aqueous solution (with 0.25 per cent procaine) has been used. Schedule A consists of 100,000 Oxford units given in five injections of 20,000 Oxford units each at two hour intervals. The elapsed time on such a program is eight hours. Schedule B consists of the same time schedule but double the amount of penicillin. Forty thousand Oxford units was given in each injection at the two hour intervals. Schedule C consists of three injections at two hour intervals. In the first injection 50,000 units is given in each buttock for a total initial dose of 100,000, followed by two 50,000 Oxford unit injections at two hour intervals. The same total unitage is achieved as in schedule B, but the elapsed time is only four hours. It was found that the shortening of the time schedule from eight to four hours resulted in a loss of almost 10 per cent effectiveness (90 per cent to 80.7 per cent) even though the dosage remained constant.

Evaluation of Treatment of Pneumococcic Pneumonia.—Thompson evaluates the treatment of 189 cases of primary pneumococcic pneumonia with sulfamerazine to indicate where sulfonamides have been inadequate in the management of pneumococcic pneumonia and to emphasize that the great majority of patients who die of pneumococcic pneumonia are above 40 years of age. Patients who die usually have cardiac or renal disorder prior to death, and many patients respond to treatment for pneumonia but die of some latent disorder which may have been aggravated by the acute illness. Twenty-three of the 189 patients had an elevation of the blood urea nitrogen above 40 mg. per hundred cubic centimeters; 14 recovered and 19 died. Fourteen of the patients who died had elevation of blood urea nitrogen on admission, before sulfamerazine was started. Only 1 fatality could be ascribed to the treatment. A method of assessing therapeutic efficacy is discussed and is mainly a matter of defining treatment failure. Sulfamerazine was found a safe and efficacious remedy.

Control of Houseflies by DDT Sprays.—Baker and his associates investigated milk and food establishments. In dairies a 2.5 per cent DDT-xylene Triton emulsion was used at the rate of 200 mg. of DDT per square foot. A complete treatment of both barn and outbuildings usually gave satisfactory control for three months or more. In restaurants a 7.5 per cent emulsion was applied to the ceiling and walls of dining rooms and kitchens at the rate of 200 mg. of DDT per square foot Excellent control was obtained for three or more months in the restaurants treated. In small food and ice cream shops, 40 to 60 feet of DDT-impregnated cord hung as a replacement for electric light pull cords, along the chains of suspended display shelves and from ceilings at locations where the cord would be accessible to the flies gave good control when fly populations were not excessive In shops with a great influx of flies, the treated strings did not bring the flies under satisfactory control.

Gelatin Solution in Shock.—Levinson and his associates studied the efficacy of gelatin solutions in the treatment of hemorrhagic shock Various brands of gelatin, gelatins with different degrees of hydrolysis and various concentrations of gelatin solutions were tried On the basis of their experiences on dogs they recommend gelatin solution for use on patients Gelatin cannot replace whole blood, nor is it a substitute for plasma, but it has value as an inexpensive, easily available agent to combat shock due to plasma loss Experience with the use of gelatin solution on patients has been favorable.

Circumscribed Chronic Suppurative Mastitis Simulating Cancer.—Tuttle and Kean observed in a woman aged 44 a hard nodular mass adherent to the overlying skin, with typical peau d'orange and retracted nipple accompanied by enlarged, hard, nontender, homolateral axillary lymph nodes A diagnosis of carcinoma of the breast and axillary metastases was made and a radical mastectomy was done. This revealed a hard, circumscribed, unencapsulated mass filled with thick, yellowish green pus During the following years this type of lesion was observed at fairly regular intervals and in numerous instances presented great difficulty in differentiation from carcinoma of the breast. All breast tumors removed at Gorgas Hospital between 1920 and 1945 were reviewed and a total of 32 cases of chronic suppurative mastitis were selected for study. Its relative incidence as compared with carcinoma was approximately 1 to 5. Simple incision and drainage is a poor operation for this disease. The best surgical treatment for a patient *with a tumor of the breast in which the differential diagnosis* rests between cancer and circumscribed chronic suppurative mastitis is as follows: First decide whether the tumor mass alone or the entire breast is to be removed, then proceed with the excision or simple mastectomy. The tumor or breast should be immediately sectioned on a separate table Examination of the tumor at this time will solve the problem in most instances. The tumor should not be incised in situ; pus, if present, will contaminate the entire wound and may prolong the convalescence If this procedure is followed, patients with this benign lesion may be spared radical treatment, whereas those with malignant tumors will not be deprived of the full diagnostic and surgical efforts required in the treatment of cancer.

Malignant Lymphoma.—Hellwig says that in the course of two decades he observed that patients with malignant lymphoma occasionally lived five years and longer after surgical removal of a single tumor. This discrepancy between occasional long survival periods after operation and the discouraging view of most surgeons regarding malignant lymphoma prompted him to review 234 cases of malignant lymphoma Analysis of 130 cases with complete clinical records followed for a sufficient length of time to be of value revealed a close correlation between the histology and life expectancy. The average duration of disease was 26 7 months It varied in the different histologic types between 3 months and 4 8 years Radiation therapy may occasionally save a life when the tumor is located in a vital part of the body inaccessible for surgery, but it will seldom prolong the life expectancy inherent in the histologic type of lymphoma Early surgical removal of a primary focus of disease offers the best chance of cure in malignant lymphoma Of 21 patients who received radical surgery for a single primary focus, 2 survived for from five to twenty years

Renal Anoxia and Traumatic Uremia Syndrome.—Darmady found 44 deaths among 10,000 casualties admitted to a casualty clearing station in England, and of these 12 were due to renal failure. Details of the first 6 of these fatal cases were published, as well as of the 2 cases in which renal failure was recognized clinically and in which recovery occurred. The present report deals with a further 6 cases of fatal traumatic uremia and 3 more cases of uremia with recovery. The etiologic factors and the similarity to other conditions have led to the conclusion that the ultimate cause of death is renal anoxia. The mechanism of the production of renal anoxia by alteration of the blood supply to the kidney by vasospasm is suggested. The dangers of overalkalization and possible help through splanchnic block are brought forward.

Chorioncarcinoma of Testis with Gynecomastia.—A soldier aged 24, whose left testis had been removed two and one half months previously for a tumor, had made a good recovery from the actual operation, but for a few weeks previous to his admission he had been losing weight and had noticed that his breasts were becoming tight and swollen. The condition of the patient rapidly deteriorated, secondary tumors appeared, and he died five weeks after admission. Tumors of the lungs, liver, kidney and para-aortic glands were sectioned and examined by various staining methods. Various sections from both breasts were also examined. The tumors had the typical microscopic appearance of chorioncarcinoma. Lyall regards the presence of early carcinoma in the hyperplastic breast as the most interesting feature of this case.

Hemorrhage from Peptic Ulcer in Child.—Wilkinson reports the occurrence of peptic ulcer in a Meckel's diverticulum in a girl aged 11 months. Complete recovery followed removal of the diverticulum.

*Potassium Thiocyanate in the Treatment of Hypertension. G. Watkinson and G. Evans.—p. 595.
*Autohemagglutination and Raynaud's Phenomenon. G. B. Forbes.—p. 598.

Folic Acid as Therapeutic Agent.—Employing folic acid in various types of blood dyscrasias, sprue and colitis, Davidson and Girdwood found that a hemopoietic response was obtained only in cases in which the bone marrow was megaloblastic, that is, in pernicious anemia, refractory megaloblastic anemia and sprue. No therapeutic changes were obtained in cases of aplastic anemia, leukopenia or thrombocytopenia. Folic acid controlled the diarrhea and produced general clinical improvement in adults with tropical sprue and idiopathic steatorrhea, but by itself it seldom restored the blood level or blood picture to normal. In none of the cases of celiac disease was any hematologic or clinical improvement noted. The clinical and sigmoidoscopic appearances in 5 cases of idiopathic ulcerative colitis were unaffected by folic acid therapy.

Potassium Thiocyanate for Hypertension.—Watkinson and Evans think that the differences of opinion regarding the value of potassium thiocyanate are due (1) to the narrow margin that exists on occasion between the therapeutic and the toxic dose of the drug, as also to the fact that a toxic rash may appear when the drug concentration in the blood is at a low level, and (2) to the fact that the coincidental arteriosclerotic disease is not as yet either recognized or understood. They review observations on 60 patients with persistent hypertension. They place the patient at rest in bed for the first fortnight or three weeks with symptomatic treatment. After the effect of this treatment on general well-being and blood pressure has been noted, potassium thiocyanate is given for from four to ten days if indications for its use are still present. At the end of one week's treatment the serum thiocyanate concentration is estimated. The quantity of potassium thiocyanate administered should be based on serum estimations. Blood pressure readings are no criterion of dosage. A scheme of dosage is given together with indications for treatment. Symptomatic relief and a significant fall in blood pressure were observed in roughly 60 per cent of the cases. The further observations of 42 patients show that the effect of thiocyanate therapy can be correlated with the phases of the arteriosclerotic process, and that whereas symptomatic relief is given and blood pressure reduction is maintained in approximately 40 per cent of the cases, the continued administration of potassium thiocyanate does not prevent the continued progress of arteriosclerotic disease.

Autohemagglutination and Raynaud's Phenomenon.—Forbes tells of an American sergeant aged 24 who was admitted to the hospital with the complaint that his fingers became blue and numb on exposure to cold environmental conditions. During the patient's stay in the hospital the weather became warmer and attacks did not develop spontaneously. It was possible to induce an attack by immersing the patient's hands in cold water. That the patient was an "autoagglutinator" was first suspected when an attempt was made to do a blood count. Capillary blood issuing from a small puncture wound in the lobe of the ear was seen to agglutinate spontaneously. It was impossible to carry out an accurate blood count, but by warming the patient's ear with a hot water bottle and using pipets and diluting fluids which had been warmed to 37 C., agglutination was temporarily prevented and a reasonably accurate blood count obtained. It was shown that the abnormal agglutinin in the patient's serum was a true autohemagglutinin, but the factor responsible for its presence was not determined. The fact that no abnormality was detected on examinations of the chest does not altogether exclude the possibility that he had had a subclinical attack of primary atypical pneumonia, a disease which was encountered among service personnel in northwestern Europe at the time of his admission. It is suggested that the Raynaud-like attacks which followed exposure of the patient's extremities to low temperatures resulted from blockage of the small peripheral vessels with corpuscular aggregations.

Rare Case of Intrathoracic Foreign Body. L. Mayer.—p. 1048.

Penicillin in Arterial and Venous Infections.—Bernard administered penicillin to 3 men between 33 and 50 and 2 women aged 54 and 63 with phlebitis, 1 man aged 57 with coronary arteritis and 1 woman aged 52 with coronary panarteritis. The total dose varied between 500,000 and 2,500,000 units. The temperature was restored to normal in thirty-six to forty-eight hours. The penicillin therapy should be continued for at least five additional days or even longer to prevent a recurrence. Drop in temperature was associated with a decisive improvement in general phenomena even in the case of severe polyarteritis. Penicillin therapy is useful in infection which causes spread of the inflammation of the vessels along the intima and by embolism. Continuation and spread of the disease may be prevented by sterilizing the blood and by maintaining asepsis of the blood. The formation of new emboli may be avoided, and new foci resulting from embolism in other organs and vessels may become disinfected. Penicillin is effective not only in thrombosis of large vessels but also in inflammation of coronary vessels. Penicillin does not effect the absorption of the clot, which requires the same length of time as when penicillin is withheld.

Pneumonoconiosis.—According to Policard, inhaled dust particles are phagocytosed in the alveoli. Dust loaded cells pass into the conjunctival spaces of the sheaths and into the lymphatics. They block the lymphatics, and edema of the sheaths results. Segmentary fibrosis of the sheaths may be partly due to collagen fibers and partly to reticulin fibrillae. The more or less fusiform thickening of the peribronchial and perivascular sheaths explains the existence of nodules in the lung, which must be distinguished from the silicotic nodules, since they do not contain hyaline fibers and cannot be detached easily from the surrounding tissue. Phosphocalcareous impregnation of the sheaths rather than calcification results from the accumulation of mineral dust, since the carbonate of lime is neither solid nor crystalline but is a combined molecular substance of protein complex, causing radiopacity of the sheath. The conjunctival layer of the sheaths loses its normal elasticity with consequent embarrassment of the respiratory movements, causing dyspnea. The dust particles interfere directly with the nutrition of the arterial wall, causing periarteritis, and accumulation of dust in the peribronchial sheaths is responsible for an indirect disturbance of the nutrition of the wall of the adjacent pulmonary artery. Sclerosis of pulmonary areas results from progressive obliteration of pulmonary arteries, and atelectasis results from progressive obliteration of the bronchi.

Streptococcic Sepsis of a Newborn Infant Whose Mother Had Mastitis During Pregnancy.—Fukas reports the history of a male infant who developed symptoms on the third day of life and who died on the fifth day of streptococcic septicemia. Necropsy corroborated the diagnosis. The mother had had mastitis of the left breast for two months before her confinement. It is assumed that streptococci were transmitted to the infant in utero by way of the blood stream. The general infection developed after the antibodies derived from the mother had been exhausted.

*Traumatic Intracerebral Hematoma: Cure After Operation. E. Vigil Sóñora.—p. 528.
*Tuberculosis of Mamma. A. Pou de Santiago.—p. 566.

Traumatic Intracerebral Hematoma.—An adult showed signs of cerebral injury twenty-four hours after having sustained cranial trauma. Diagnosis of intracerebral hematoma was made on evidence presented by encephalography, namely the displacement of the pineal body and of the left ventricle. The operation consisted in evacuation of hematoma near the ventricle. One week later the cerebral symptoms reappeared. Encephalography showed reformation of the hematoma, which on this occasion was drained by aspiration, resulting in final cure of the patient.

Tuberculosis of Breast.—Pou de Santiago reports the occurrence of primary tuberculosis of the breast in 3 adult women. In 1 of the patients the clinical diagnosis was confirmed by the results of the roentgen examination of the canalicular system of the breast by Leborgne's method. The therapy consisted in surgical removal of the breast and the general therapeutic regimen.

*Paralytic Inguinal Hernia. R. Zúñiga Latorre.—p. 195.

Paralytic Inguinal Hernia.—This condition, a relatively frequent complication of appendectomy, has not been previously described. It is due to paralysis of the muscles of the inguinoabdominal region caused by lesions to nerves during the operation. The nerve lesion manifests itself by a permanent neuralgia following the operation and with later formation of an inguinal hernia. Prevention consists in avoiding injury to the nerves. The treatment of the condition requires freeing the nerves from the scar and the performance of a Bassini herniotomy employing a pedicle of fascia from the patient's own larger oblique muscle. Seven cases are reported.

*Gonorrheal Peritonitis in Upper Part of Abdomen. L. W. van Ravesteyn.—p. 808.
*Acute Pancreatitis as Complication of Epidemic Parotitis. J. J. Spittuler.—p. 814.

Gonorrheal Peritonitis.—The first of the 2 patients presented by van Ravesteyn was a woman aged 29 who suddenly developed signs of peritonitis in the upper abdomen on the right side. The patient had gonorrhea and an old salpingitis. The symptoms, which were diagnosed as gonorrheal perihepatitis, were counteracted by 160,000 units of penicillin administered by eight intramuscular injections in the course of a day. The symptoms of the second patient were counteracted by 200,000 units of penicillin. Discussing the various clinical pictures that can be produced by the gonococcus within the peritoneum, Ravesteyn points out that gonorrheal perihepatitis was described as a separate entity by Stajano in 1920. Trauma in the form of surgery, gynecologic examination, coitus or irrigation may be etiologic factors. The differential diagnosis must consider cholecystitis, pyelitis, nephrolithiasis, appendicular subphrenic abscess, pneumonia of a lower lobe and extrauterine pregnancy.

Acute Pancreatitis as Complication of Mumps.—In the course of an epidemic of mumps in 1946 it was realized that mumps is not as harmless a disorder as it is generally assumed to be. Spittuler reports that a boy aged 8 exhibited the symptoms of acute pancreatitis with high fever, severe pain in the epigastrium and in the left hypochondrium with radiation toward the back and vomiting. The symptoms subsided in five days. Pancreatitis usually develops about a week after the parotid swelling, but it may also precede it. Examination of the urine for the presence of sugar is advisable for some time after the recovery of the patient.

Book Notices

The Philosophy of Insanity. By a Late Inmate of the Glasgow Royal Asylum for Lunatics at Gartnavel. With an Introduction by Frieda Fromm-Reichmann, M.D. Cloth. Price, $2.50. Pp. 116. Greenberg, Publisher, 201 E. 57th St., New York 22, 1947.

This remarkable autobiographic commentary was written in 1860 by an anonymous recovered psychotic patient. Dr. Fromm-Reichmann, interested in exposing the thesis that the psychologic experiences and modes of expression of psychotic, neurotic and "so-called normal" individuals differ not in kind but in degree, has uncovered this work, which offers impressive support to her thesis. While the author, a layman, reflects in his writing a number of the misconceptions current to the psychiatric thinking of his time, his concept of mental disorder is in great measure in keeping with modern thinking. He insists that "the line that separates sanity from insanity is invisible, and there are as many kinds and degrees of the disease as there are sufferers."

The description of the delusional mental state during recovery from a manic attack has the peculiar quality dependent on the intense suffering experienced by the writer. His remarks on the care of the insane, his discussion of popular misunderstanding about the nature of mental disorder and the stigmatization of the mentally ill might appear in a present day publication. His discussion of qualifications of hospital attendants for the insane and standards of pay should be read by the legislators who provide funds for our public institutions for care of the mentally ill. The author's personal experience in Gartnavel indicates a very high order of care for the patients in this institution nearly a hundred years ago.

The incisive, at times epigrammatic, style of writing reflects the author's sharp perspective and deep feeling about the sufferings created by the distortions of the mentally ill. "There is nothing more wicked than virtue out of its wits, nothing more cruel than humanity run mad. . . . Nothing assimilates man more closely to the fiend than religious fanaticism."

In the discussion of bodily and mental health, says the writer, "In every description of sickness and pain which afflict the body the mind is a participator"; so it appears that psychosomatic concepts have a long history. This book is well worth the reading time of every physician and medical student.

Éducation physique, sports et tuberculose pulmonaire. I. La tuberculose des sportifs. II. La prophylaxie de la tuberculose pulmonaire par les exercices physiques. III. La gymnastique et les sports dans le traitement de la tuberculose pulmonaire. Par le Docteur Pierre Weiller. Paper. Pp. 320, with 31 illustrations. Vigot Frères, 23 rue de l'École-de-Médecine, Paris 6ᵉ, 1946.

This volume is devoted to pulmonary tuberculosis as it occurs in persons engaged in physical education and athletics. The author, having been an athlete himself, became interested in this subject, and, having been the physician of several societies of physical education and sports, he had an unusual opportunity to observe tuberculosis among those engaged in these activities. The histories of 207 cases are reported. The author is particularly interested in determining what part athletics plays in the development of pulmonary tuberculosis. This he found extremely difficult. For example, in one person who held a regular position engaged in several sports during his spare time the question was whether his tuberculosis was due to the regular job or to the sports. A boxer who became indignant because he had been defeated in a match began to lose weight, to cough and to develop serious pulmonary tuberculosis. All cases in which tuberculosis developed in athletes in whom he thought some such circumstance might have precipitated the disease, rather than the sports, were eliminated.

One hundred and forty-six cases are presented which the author considers valuable from the point of view of athletics having played a role in the development of the disease. Twenty-seven cases occurred among professionals in physical education and athletics. Therefore the author points out that tuberculosis does not respect such persons. The average age of these patients was from 30 to 35 years. With two exceptions the disease was of long standing—from four to fifteen years. The author states that the impression one gets from the study of pulmonary tuberculosis among the professional sportsmen is that it is a slowly progressive disease. He warns that they must be kept under the close observation of the physician, as the disease in some of them becomes contagious and may contaminate their colleagues.

One hundred and nineteen cases of tuberculosis among amateur athletes are presented. Therefore it is strongly recommended that adequate examinations be made periodically of every amateur. From a description of these 119 cases it becomes apparent that they do not seem to be significantly different from those which one regularly sees drawn from the general population. The treatment administered, both among the professional and among the amateur athletes, is discussed in considerable detail, and a number of x-ray reproductions are presented to show lesions before and after treatment.

The second part of the book is devoted to the prophylactic value of physical education and athletics in pulmonary tuberculosis. The author believes that much tuberculosis can be prevented by certain technics in this field. Part three consists of a discussion of physical education and athletics in the treatment of pulmonary tuberculosis. Along with the benefits which he thinks may be accomplished he calls attention to certain dangers.

The Preservation of Proteins by Drying, with Special Reference to the Production of Dried Human Serum and Plasma for Transfusion. By R. I. N. Greaves. Medical Research Council Special Report Series No. 258. Paper, 2s. Pp. 54, with 25 illustrations. His Majesty's Stationery Office, York House, Kingsway, London, W. C. 2, 1946.

Increasing use of proteins in biologic research and their rapid adoption in therapy have focused attention on the problems concerned with the handling of proteins. If protein preparations are to have a wide clinical use distribution must be made in a convenient and stable form which permits adequate standardization and insures reproducible results. A notable contribution to this requirement is the development of methods for reducing proteins to the dry state with a minimum of alteration in chemical or biologic properties. This book presents the application of vacuum drying from the frozen state to the problem of protein preservation. The author has made important contributions to the field and presents here the results of his own research together with the application to the large scale drying of human serum and plasma during the past six years in England. He reports on the drying of over 350,000 units of plasma and serum, from June 1940 to September 1945 with an overall loss of less than 0.5 per cent. The historical review will be valuable to those who are interested in the development of vacuum drying. Probably by necessity it omits some of the more recent developments in the United States; although many of them are related to large scale drying of penicillin, they are directly applicable to the drying of proteins. Although most of the theory of the kinetics of vacuum systems is omitted, the experiments, observations and practical applications recorded represent a contribution to a field in which opinions are still more numerous than the results of controlled experiments.

A History of Scientific English: The Story of Its Evolution Based on a Study of Biomedical Terminology. By Edmund Andrews, M.D. Cloth. Price, $7.50. Pp. 342, with 18 illustrations. Richard R. Smith, 20 E 39th St., New York 16, 1947.

This book was written by a surgeon of the first rank, a scholar of broad interests and a gentleman of character, attributes that might be anticipated in the son of E. Wyllys Andrews and the grandson of Edmund Andrews. When Dr. Edmund Andrews died late in 1941 he had completed the manuscript which has now been published. Arno Luckhardt has written a foreword in which he admits that he put off reading the bulky manuscript for some time, particularly since the title did not portend exciting reading. But the perusal of the first few pages sufficed to impel him to continue the task with growing enthusiasm. Actually the book affords delightful reading and, while quite advanced and thorough in all that pertains to the knowledge of philology, its breadth, the versatility of its approach, the wide sweep of the correlations, the skilful blending of personal observation and knowledge with accepted fundamentals of the science of words all contribute to make this an unusually interesting book.

It is fortunate that the professional life of the author centered about medicine and surgery, for he has made use of the development of the medical sciences to illustrate the growth of language in general, and here his contributions are many and original as well as authoritative. One is apt to forget that words are the only tools that we possess in our mental workshop and so the study of words is something more than merely of historical or vocational interest.

Quite apart from its textual content, the contribution is decidedly a personal and a very human one. Andrews' wide interests in diverse fields are constantly brought into play by way of illustration, by allusion and interpretation. So, for instance in his excellent discussion of the growth and development of the languages of the Mediterranean basin, the impact of the Aryan invasion, and in tracing the growth and development of our modern languages from these origins. Here Andrews could with profit turn to the Polynesians to illustrate in a living model what probably happened two or three thousand years ago among people who have vanished. But it is by just such fascinating excursions that Andrews provided the necessary contrast, the alluring diversions that make the reading of the work a pleasure and not a chore.

In all this Andrews is revealed not only as the sound scholar and broadly interested scientist but as the very human person with a grand sense of humor, a keen appreciation of organic continuity and integration, and the able writer of a truly unique contribution to both the science of medicine and the science of words. It is a contribution in which we can take pride.

The Peripheral Circulation in Health and Disease: A Study in Clinical Science. By Robert L. Richards, M.D. Foreword by J. R. Learmonth, C.B.E., Ch.M., F.R.C.S.E., Professor of Surgery and Clinical Surgery, University of Edinburgh, Edinburgh. Cloth. Price, $6. Pp. 153, with 104 illustrations. William Wood & Co., Mt. Royal & Guilford Aves., Baltimore 2, 1946.

This monograph contains studies on peripheral circulation in normal limbs, in the limbs of those suffering from peripheral vascular disease, from peripheral nerve injuries or from exposure to cold. The author reviews the evolution of knowledge in this field and builds his own observations on this foundation. Most valuable are his observations on the vascular changes after peripheral nerve injuries. These were made in a peripheral nerve injury center which contained about 350 patients. Equally lucid and instructive are the studies on immersion limb. This is a logical, lucidly written book, excellently printed and illustrated. It is representative of the best type of clinical physiology, in which Sir Thomas Lewis excelled. For residents and young vascular surgeons there could be no better instruction in fundamental knowledge or stimulus for future research.

Actions of Radiations on Living Cells. By D. E. Lea, M.A., Ph.D., Prophit Student of the Royal College of Surgeons, Cambridge. Cloth. Price, $4.50. Pp. 402, with 61 illustrations. Macmillan Company, 60 Fifth Ave., New York 11; Cambridge University Press, 200 Euston Rd., London, N. W. 1, 1947.

The author states that his intention in writing this book was to give an account of certain of the simple and most fundamental actions of x-rays through ionizing and radiations on living cells. This book is one of an increasing number of publications that are being written. The college student and the medical student of the future must be familiar with atomic and nuclear energy and the mechanism of their radiations. The text is difficult to understand, even though the author states that large portions of it have been written in an elementary fashion. The study of effects of radiations on viruses, genes and chromosomes is difficult to understand and therefore will be difficult reading for the average radiologist. The book does not contain any of the investigations on the radioactive isotopes and, looking over the bibliography, one sees an occasional American author who has been quoted on his work in radiobiology. However, many radiobiologists and geneticists are not included in the bibliography, especially some of those who have been contributing to the literature in the last few years. This estimate may not seem fair to the author, but it is felt that the average radiologist and radiotherapist who is using x-rays, gamma rays and radioactive isotopes will find the information contained in this book difficult to understand.

Theory of Occupational Therapy. By Norah A. Haworth, M.A., M.R.C.S., L.R.C.P., Industrial Medical Officer, and E. Mary Macdonald, Principal, Dorset House School of Occupational Therapy. With foreword by Sir Robert Stanton Woods, M.D., F.R.C.P., Physician in charge of the Department of Physical Medicine at the London Hospital, London. Third edition. Cloth. Price, $2.50. Pp. 158, with 75 illustrations. William Wood & Co., Mt. Royal & Guilford Aves., Baltimore 2, 1946.

The value of occupational therapy in the therapeutic regimen for mental patients and those with tuberculosis and heart disease is widely accepted. More recently it has proved useful together with physical therapy in regaining function in extremities affected by disease or trauma. This short book outlines for the student occupational therapist the theory of application for these various groups of patients, including suggested lists of projects which may be used and selected illustrations of apparatus. Although primarily written for occupational therapists, the physician who prescribes occupational therapy will find this a convenient work of reference.

The Unconquered Plague: A Popular Story of Gonorrhea. By Harry Wain, B.S., M.D., M.S.P.H. Paper. Price, $1.50. Pp. 119. International Universities Press, 227 W. 13th St., New York 11, 1947.

With a matter of fact attitude that is more impressive than that taken by the alarmists, the author of this little volume has done an excellent job of presenting the problem of venereal disease control, and specifically gonorrhea. It is a dispassionately frank discussion of the way in which this "commonest plague of mankind" is perpetuated. There is no false overemphasis on the sordid aspects but neither is their importance overlooked. The historical data are presented in a chronological account that makes extremely interesting reading. The volume contains ten chapters in which the great antiquity of gonorrhea and its persistence down through the ages, its identification but resistance to earlier treatment methods, the ways in which it may affect the human body, the great hope for its final elimination as a result of the advent of penicillin, the prostitution problem and facts about prophylaxis are presented in a smoothly written text. A brief glossary provides helpful guidance. The volume can be recommended by the physician to lay readers with the certainty that much helpful orientation regarding the problem of gonorrhea will be provided.

The Problem of Lupus Vulgaris. By Robert Aitken, M.D., F.R.C.P.E., F.R.S.E., Physician to the Skin Department, the Royal Infirmary of Edinburgh. Cloth. Price, $4. Pp. 69, with 31 illustrations. William Wood and Company, Mt. Royal & Guilford Aves., Baltimore 2, 1946.

"This small book is written in an attempt to help the sufferer from lupus and inasmuch needs no apology. It presents the experience of thirty years' practice in the treatment of such patients." With such a humble beginning to the preface of this book one hesitates to be critical. However, for all it contributes to the knowledge of "lupus"—it is assumed that the author means lupus vulgaris—it might as well have been written thirty years ago. The illustrations are without value because they are badly out of focus for the most part and the color reproductions are meaningless. There is no discussion of the histopathology of the disease or of the modern methods of treatment. It is difficult to understand why an American publisher would offer this volume at this time for this price.

Et Bidrag til Kampen mod Kræften? Udarbejdet paa Basis af Forsøg udført i Aarene 1939-46. A Contribution to the War Against Cancer? Based on Experiments Carried out in the Years 1939-46. By H. G. Garde. Paper. Pp. 80, with 20 illustrations. Ejnar Munksgaard, Nørregade 6, Copenhagen, 1947.

This booklet was privately printed by the author, Mr. H. G. Garde of the United Steamship Company Limited of Copenhagen. It describes an effort, greatly hampered by wartime conditions in Denmark, to gather data in support of the theory that "cancer may be a disease which arises because the human cellular system, on account of deviations in the metal salt content of the blood regarded from the point of view of high frequency, is unable to utilize the energy conveyed thereto by magnetic oscillations which, coming from space, act upon us night and day." While the sincerity of the author is quite apparent, the accuracy of the methods used in the various determinations is open to question.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

RESUSCITATION OF THE ASPHYXIATED

To the Editor:—I should like to inquire as to the present status of oxygen versus oxygen-carbon dioxide mixtures for use in emergency resuscitation of the asphyxiated. Considerable difference of opinion is present in various textbooks on this subject. For example, Johnstone in "Industrial Medicine" recommends the use of carbogen, while Flagg in his "Art of Resuscitation" recommends the use of pure oxygen. Similar differences of opinion appear in other textbooks, and an informal query among various anesthesiologists has raised a similar divergence of opinion. Specifically, my problem relates to the resuscitation of persons overcome by carbon monoxide as a result of exposure to illuminating gas and to the resuscitation of persons overcome in burning buildings, a mixture presumably of carbon monoxide, carbon dioxide, smoke and irritating gases. I should also like to inquire as to the cause of a phenomenon which is a common experience among firemen at the local department and which I myself have observed on numerous occasions. Frequently when firemen have been working in a smoky atmosphere or one with a low oxygen content they feel fairly well as long as they continue exposed; or, if they feel faint, they are almost invariably able to reach the street. But as soon as they are exposed to fresh pure air, they lose consciousness with extraordinary quickness.

William D. Claudy, M.D., Washington, D. C.

Answer.—The following statements are based on a study made under strictly controlled conditions on groups of dogs large enough to determine by statistical means whether a difference observed would be likely to occur by chance. Only those results obtained when the gas under study was given by mechanical means to insure a relatively constant minute volume of pulmonary ventilation will be cited. Eighty-two dogs were exposed to 0.3 per cent carbon monoxide in air until the first antemortem gasp occurred and then were "resuscitated" with 100 per cent oxygen; 84 dogs similarly treated were "resuscitated" with 7 per cent carbogen (7 per cent carbon dioxide and 93 per cent oxygen). Sixty-nine per cent of the oxygen treated and 66 per cent of the carbogen treated groups survived, and the incidence of neurologic sequelae was 34 per cent in the oxygen and 35 per cent in the carbogen group. In the case of uncomplicated obstructive asphyxia a significant difference was not found in the immediate percentage of survival when 100 per cent oxygen, 7 per cent carbogen or even air was used.

As far as immediate survival is concerned, the important point is to get oxygenated blood to the heart as quickly as possible. This is more dependent on the minute volume of oxygen that is moved into and out of the lungs per unit of time without injuring the lungs than on any other factor. The most important factor in determining the incidence and severity of neurologic sequelae with equivalent degrees of harmfully low oxygen saturation of the blood is the duration of the anoxia.

It is true that carbon dioxide increases somewhat the rate of clearance of carbon monoxide from the blood; but the results showed that the difference in rate of clearance between 100 per cent oxygen and 7 per cent carbogen is of no real physiologic significance in reference to survival or sequelae. Carbon dioxide stimulates the "normal" respiratory center; but it does not stimulate the definitely anoxic respiratory center, and the resuscitation of the respiratory center is of secondary importance in resuscitation. The importance of starting the respiratory center has been overemphasized. The important point is to get oxygen to the heart and brain as quickly as possible by providing as much pulmonary ventilation for the first few minutes as the lungs will take without rupture. Whether the gas is 100 per cent oxygen, 7 per cent carbogen or air is without real significance, except that a high concentration of oxygen would be advantageous in the presence of pneumonosis or pulmonary edema.

Persons are more likely to collapse after entering the air from a smoke filled place for two reasons: one, the irritating gases and excitement reflexly stimulate the circulation, and two, which is probably more important, the effects of anoxia accumulate and are not pronounced enough to cause collapse until fresh air is reached. To this may be added the "lightheadness" caused in a normal person by taking several deep gasps of air in rapid succession. These explanations, however, are theoretical, and no one has actually proved them to be true.

TREATMENT OF CARDIOVASCULAR SYPHILIS

To the Editor:—A white man aged 56 has syphilitic heart disease with aortic insufficiency without signs of coronary involvement or heart failure. He has received bismuth injections weekly for the past year. He has not had arsenicals or other treatment. The heart is 0.5 cm. increased in transverse diameter. Should this patient be given any other medication and for how long? How long should bismuth be continued? Repeated blood Mazzini and Kolmer serologic tests are 4 plus positive.

M.D., New Jersey.

Answer.—A patient such as described in the query without congestive heart failure and with a year of preparatory heavy metal treatment probably would be benefited by the cautious and judicious use of a trivalent arsenical. In selection of drug and route there is a choice between an intramuscular preparation such as bismuth arsphenamine sulfonate (bismarsen) or an intravenous preparation such as a phenarsine derivative (mapharsen or dichlorphenarsine hydrochloride), either of which would be effective. Subtherapeutic doses should be used and the patient should be carefully observed for the first three or four weeks of treatment for any evidence of intolerance. Bismarsen should be given once a week starting with a dose of 0.05 to 0.1 Gm. intramuscularly for the first month dissolved in the solvent supplied, after which the dose may be increased to 0.2 Gm. once a week. Forty weeks of continuous treatment with bismarsen, followed by a course of ten weeks of bismuth subsalicylate could form the second year of treatment in your patient.

Oxophenarsine hydrochloride (mapharsen), if used instead of bismarsen, should be employed in weekly dosage intravenously of 0.01 to 0.02 Gm. for the first month, followed by a maximum weekly dose of 0.03 Gm. Courses of ten weeks of such treatment alternated with eight weeks of bismuth subsalicylate continuously throughout the next year would be a satisfactory alternative type of treatment to the one described.

If the patient is intolerant to arsenicals they should be stopped and treatment continued with bismuth subsalicylate alone. In general, however, patients with cardiovascular syphilis do better and have a longer life expectancy if it is possible to employ one of the trivalent arsenicals. Total treatment should cover a period of not less than two years, but further specific therapy beyond that time should be suited to the individual case.

Penicillin is considered at present to be contraindicated in cardiovascular syphilis, though adequate study of its use after prolonged preparatory treatment has not been carried out. The presence of a repeatedly positive blood serologic test is the usual finding in cardiovascular syphilis, and it would be the exception rather than the rule that it would be reduced to negativity by treatment.

VAGINAL TAMPONS DURING MENSTRUATION

To the Editor:—What is the present consensus regarding the use of vaginal tampons during menstruation?

M.D., Iowa.

Answer.—The question of vaginal tampons is not settled. Many writers are enthusiastic about the use of these tampons but others are rabidly against them. K. J. Karnaky (*West. J. Surg.* **51**:150 [April] 1943) examined 218 women who had used tampons regularly during menstruation for a year or more and failed to find any irritation, discharge, vaginitis or cervicitis. On the contrary, in many cases in which vaginal disturbances were present before the use of the tampons, normal conditions were restored. In no instance could evidence of obstruction of the flow be obtained, because none of the women developed uterine cramps. M. J. Thornton (*Am. J. Obst. & Gynec.* **46**: 259 [Aug.] 1943) interviewed and examined 110 women who used vaginal tampons for absorption of the menstrual flow every two months from one to two years. There was no evidence of any irritation of the vagina or the cervix. No woman acquired a trichomonas or yeast infection during this investigation. The incidence of trichomonas infection was 3.63 per cent, which is less than the average given in most statistics. J. M. Singleton and H. F. Vanorden (*West. J. Surg.* **51**:146 [April] 1943) sent a questionnaire to 3,400 doctors in the United States and Canada to determine their attitude on the use of tampons as a menstrual hygiene measure. The physicians were 4 to 1 against recommending menstrual tampons. There was almost unanimous opinion against tampons in virgins in the belief that it created sex consciousness and might stimulate eroticism and the habit of masturbation. Also the difficulty of application was stressed. Twenty per cent of the physicians reported cases presenting pathologic changes varying from mild vaginitis to pelvic infection. The authors conclude that there is a definite potential source of infection in the habitual or occasional practice of menstrual tamponage and that preexisting infections are thereby aggravated.

R. L. Dickinson (The Journal, June 16, 1945, p. 49) says that sales of tampons make up about 10 per cent of sales of commercial napkins. The sales are on the increase. In 1943 five times as many tampons were sold as in 1937. A 1944 survey in twenty-six cities covered interviews with 2,500 women purchasing two kinds of menstrual protectives. Of these 24 per cent used tampons, including the third with exclusive dependence and the two thirds with supplement of a napkin part of the time. This use was equally distributed between married and single women.

Dickinson concludes that the physician asked by the patient about tampons can answer that healthy women with average flow are using them increasingly with comfort but may also need the outer guard the first day; second, that doctors lack reports on a series of local examinations on those who reject them after trial to discover the reasons, and, third, that in her own case her local examination will show, or has shown, absence of any undue tenderness, inflammation, cramps or lack of room which could defer or prevent the use of the tampon.

A new disturbing factor in the use of vaginal tampons was presented by A. E. Taft (*West. J. Surg.* **51**:342 [Aug.] 1943). He found inclusion bodies in the vaginal epithelium and suggests that they may arise from use of commercial tampons and vulvar pads. This is indicated by the findings of Conant, Wagner and Rackemann that a great part of the cotton, wool, kapok and other materials used in furniture, pillows and mattresses contains spores. They were found without exception in kapok, a vegetable fiber. Some of the tampons contain a core of jut, which is also a vegetable fiber. Direct information from the manufacturer of a group of these products is that, "as far as we know, sterilization is not practiced on any tampon due to the fact that it has been found to impede absorption." Chemical treatment and high pressure are depended on to eliminate the organisms present in raw cotton. The two necessary factors for the germination of spores are warmth and moisture, both of which would be supplied in the use of tampons or pads.

TRICHINOSIS

To the Editor:—A white married woman aged 34 still has evidence of trichinosis after nineteen weeks. She drives her car and is living a fairly normal life except that she tires easily and frequently develops small painful areas almost anywhere in her body from the neck to her ankles. Sometimes red spots develop, some flat and some raised like an urticaria. These do not itch but are painful. Pains in the muscles practically disappeared three or four weeks ago but now have returned. She is eating well and gets vitamin B_1 in heavy doses and liver injections; her bowels move daily with excellent results. The urine is normal in amount, chemical tests are normal, that is, the specific gravity is 1.018, sugar negative, albumin negative and reaction slightly acid. I am sure of the diagnosis from the positive test I got. The eosinophil count was up. At present eosinophils are normal. The blood picture is normal. Can you advise me regarding further treatment?

Elmer W. Clarke, M.D., Norton, Mass.

Answer.—If the patient has proved trichinosis, there is no specific therapy available for the disease. It is not unusual for patients to have intermittent aches and pains of the striated muscles for months after the tissues have been invaded. The type of skin lesion of the patient described is an unusual manifestation of chronic trichinosis. Supportive measures for the relief of pain are all that can be recommended.

TREATMENT OF SPASMODIC TORTICOLLIS

To the Editor:—A white man aged 50 has had torticollis since September 1938. The head is pulled down and to the right and there is a compensatory spinal curvature. Treatment has included diathermy, foreign protein, hypnotism, section of the left spinal accessory nerve and muscle stretching. As a test before operation he was anesthetized with evipal and the neck was straightened as the muscles relaxed. Although never a drunkard, he drank more than moderately and has been diagnosed as having a possible resultant cerebral lesion as the cause of his wry neck. There are no other signs of any systemic disease. Mental adjustment to life is good but to the torticollis poor.

Ellis M. Markell, M.D., Harrison, N. Y.

Answer.—Torticollis is one of the more poorly understood and most difficult conditions to treat in the field of medicine. Although many such cases are ascribed to psychogenic factors, these patients usually respond poorly and at best temporarily to psychotherapy. Usually the best that psychotherapy accomplishes is to make them accept their disability philosophically and become better adjusted to the situation. Certainly many of these cases are the result of a lesion in the basal ganglions of the brain. In most instances the lesions are encephalitic in nature. Medical therapy is of little avail. In a few cases surgical treatment has proved beneficial. However, section of the spinal accessory nerve alone is seldom adequate surgical treatment. The best results have been seen when section of the spinal accessory nerve has been combined with section of the upper three anterior roots of the cervical spinal cord on both sides. This is a major procedure and should be attempted only by a skilled neurologic surgeon. Furthermore, it is too much to expect that the results of such a destructive procedure could be a perfect cure. Theoretically extirpation of the representation of the neck from the contralateral motor area of the cerebral cortex should give relief from this condition, but such a drastic surgical procedure has never been thoroughly tried. The treatment of spasmodic torticollis is far from satisfactory, and the majority of patients must become adjusted to their disability as best they can.

UNEQUAL MATURATION OF YOUNG GIRL

To the Editor:—I have under my care a girl aged 15 years. Her development has not progressed according to expectations. From the waist down her development is perfect, but the upper half of her body isn't matured for her age. She is thin; the left breast is much smaller than the right, yet even this one is not fully developed. The right incisor is a milk tooth and has no permanent one under it. She is alert, bright and active in everything, including sports and social activities. Is there any form of therapy that might help develop her without affecting her endocrines? I have hesitated to use the estrogens because her menses are normal. I am afraid of antihormones and antipituitary effects. It all sounds like hypo-ovarian function but I have preferred to wait and see what nature would do. Am I justified in continuing this way?

M.D., Connecticut.

Answer.—Maturation of the various parts of the body frequently proceeds in an irregular manner, so that if viewed at any one stage of development the patient may seem distinctly abnormal. This irregular maturation may even be manifested, as in the patient described, by unequal size of the breasts. Usually the size and form of the body attained at maturity are not far from normal in such cases, and considerable change may take place after the age of 15 years. If the menses are normal in all respects there is little reason to suspect hypo-ovaria, although endometrial biopsy would be required to exclude anovular bleeding with certainty.

The rare condition known as progressive lipodystrophy is to be considered. This is characterized by a progressive thinning of the face, upper part of the body and arms, caused by disappearance of subcutaneous fat in these parts beginning in childhood. In facial hemiatrophy and sometimes in scleroderma there is a similar but more complete loss of subcutaneous tissue. There is no adequate treatment for any of these entitites.

Whatever the diagnosis, observation is advised. If the condition progresses, it is likely to be lipodystrophy; if symptoms regress, the patient is probably a normal person with somewhat irregular maturation. No endocrine therapy is indicated.

TREATMENT OF RADIUM BURN

To the Editor:—A man aged 50 had an epithelioma on the dorsal surface of his right hand, which was treated with radium in 1942. A violent radium burn resulted which is now about ½ inch in diameter. A raw surface around the lesion is adherent to the dorsal surface of the hand. A biopsy Dec. 5, 1946 eliminates the possibility of cancer. What is the proper treatment?

L. G. Blackmer, M.D., Hooker, Okla.

Answer.—The best treatment for a case like that described in the query is plastic surgery. One may expect complete healing in the hands of a competent plastic surgeon.

The use of radon ointment has recently been advocated in the skin lesions due to the roentgen ray or radium but convincing evidence that it is effective is lacking. The danger of malignant degeneration in a trophic lesion such as that described in the query renders prompt removal the only safe method of treatment.

LYMPHOBLASTOMA AND PREGNANCY

To the Editor:—A white woman aged 37 developed a reticulum cell lymphosarcoma following a normal first pregnancy and labor. Symptoms developed one week post partum. Is there any known relationship between pregnancy and lymphoblastoma? Have any of the endocrine secretions been known to affect the course of this disease?

M.D., New Jersey.

Answer.—There is no evidence to show that pregnancy has any effect on the development or progression of lymphoblastoma. It has not been demonstrated that endocrine secretions have any effect on the course of lymphoblastoma.

THE LONGEVITY AND MORTALITY OF AMERICAN PHYSICIANS, 1938-1942

A Preliminary Report

LOUIS I. DUBLIN, Ph.D.
and
MORTIMER SPIEGELMAN, F.A.S.
New York

The centenary of the American Medical Association is a good occasion to review the longevity and mortality of physicians. It is valuable to learn what the men and women of the profession, dedicated to protect the health of others, have accomplished in protecting themselves. Such information is of importance for many reasons. It bears directly on the problem of replacement in the profession. From the economic point of view, the untimely death of physicians represents a material waste because of the large investment of time and money required to enter the field of medicine. Knowledge of the causes of death of physicians may well point the way to effective preventive measures.

The present study is based on the records of active and retired living physicians and on their deaths during the five year period 1938 through 1942 on file with the American Medical Association.[1] At the middate of this period, July 1, 1940 there were 175,159 living physicians in the country. Their distribution, according to sex and age is presented in table 1. Slightly more than one half of the physicians were 45 years of age or over. The average age of the men is 48.0 years, about one year less than that of women physicians. Of the total physicians entering this study, approximately 165,000 were actively engaged in their profession according to the census of 1940, the rest being for the most part on the retired list; the average age of these active physicians is 46.0 years. As might be expected, this average is considerably higher than that of all employed persons, namely 38.6 years.

A LIFE TABLE FOR PHYSICIANS

The first result emerging from the present investigation is a life table for physicians separately for men and for women. This life table shows the average years of life remaining at each present age; this is more commonly designated "the expectation of life." Speci[illegible]en values of the expectation of life for physicians are [illegible] in table 2. For purposes of comparison there [illegible]n included corresponding values of expectation of life for white persons in the general population, also for the period 1938-1942.

The average young physician entering his profession at age 25 has forty-three and a half years of life before him. This roughly represents the average professional career of physicians under current conditions of mortality. On reaching age 35 he still has on the average almost as many years remaining as he has already lived. In midlife, at age 45, the average physician may expect a further quarter century of lifetime. Almost twelve additional years of life remain to the average physician attaining age 65, a frequent age for retirement. Women physicians start out with an advantage of three and a half years over men at age 25, but this is reduced to less than one and a half years at age 65.

Young physicians have only a slightly greater expectation of life than white persons of the same ages in the general population. At age 25 physicians have the better outlook by about one quarter of a year, but this small advantage is lost even before midlife is reached. From age 35 onward the prospective lifetime for physicians is somewhat less than that for white persons in the general population, but the differences are not significant.

The present experience may be compared with an earlier life table for physicians for 1925.[2] For example, at age 30 the expectation of life has increased from 38.01 years in 1925 to 38.86 years in 1938-1942, a gain of 0.85 year. This improvement was not quite as great as that for white males in the general population of the country, who experienced meanwhile a gain of 1.35 years. The improvement in longevity for physicians was confined largely to ages under 50 years. The higher ages showed very little change from the earlier to the later period.

MORTALITY FROM ALL CAUSES COMBINED

In this preliminary study consideration is limited to the experience of the male physicians, who constitute 96 per cent of the total. Among all male physicians at ages 25 and over the death rate was 20.5 per thousand during the period 1938-1942, i. e. about 2 per cent per annum. Considered with regard to age, the death rates advanced from 1.7 per thousand at ages 25 to 34 years to 10.8 at ages 45 to 54 and then to 129.1 at ages 75 and over. These findings may be compared with the results of the study by Emerson and Hughes, which was based on records of the American Medical Association for 1925.[3] As is indicated in table 3, male physicians under 45 experienced a 37 per cent decrease in their mortality from 1925 to 1938-1942, while those at the higher ages showed a mixed picture. At ages

45 to 54 an improvement of 9 per cent is shown; but this was offset by a setback of 11 per cent at 55 to 64. The small increase at ages 75 and over may be due to a rise in the average age of physicians within this age range. Some satisfaction may be found in the fact that the rate of improvement in mortality among the younger physicians was greater than that for white males generally. On the other hand, there was some decrease in mortality among white males at the older ages in the general population.

In 1938-1942 the death rate for male physicians at all ages 25 and over was 2 per cent greater than that for white males of the same ages in the general population[4] (table 4). This close correspondence between the mortality of physicians and white males generally has been found in other studies. However, striking differences become evident for specific age periods. At ages 25 to 34, for example, the death rate for male physicians is only three fifths of that for all white males of the same ages. This advantage of physicians wears off rapidly with advance in age. At ages 55 to 64 physicians have the higher rate by 11 per cent and at 65 to 74 by 5 per cent. The death rates for the two groups are practically identical at ages 75 and over.

TABLE 2.—*Expectation of Life for Physicians Compared with That for White Persons in the General Population of the United States, 1938-1942; Men and Women Separately*

Present Age	Men		Women	
	Physicians	United States White	Physicians	United States White
25	43.54	43.31	47.10	46.86
30	38.86	38.83	42.43	42.29
35	34.21	34.40	37.77	37.78

75	7.22	7.25	7.48	8.02
80	5.55	5.44	5.37	5.96

If we may be permitted to speculate a bit, the relatively low mortality of young physicians may reflect two circumstances. In the first place most of them are drawn from the better situated social-economic classes, which generally experience lower death rates. Secondly, only those young men in a good state of health can undertake and survive the strenuous requirements of a modern medical education. As their years of practice roll on, the effect of their professional activities shows itself in increasing degree in death rates approaching those of the general population. Toward the close of their professional life the accumulated strains from previous years, as well as current demands, appear to raise their mortality to a level above that of the general population. Those physicians who have managed to survive into late life, where they experience about the same mortality as the general population, are presumably the hardier individuals who may be benefiting from a better heredity or from the advantages of a more favorable environment.

* From Emerson and Hughes[3] The death rate at ages 25 and over has been adjusted on the basis of the age distribution of male physicians in 1940

THE CAUSES OF DEATH AMONG MALE PHYSICIANS

Light on these considerations is thrown by the facts of mortality according to cause. Fortunately, the causes of death were ascertained in all but 208 cases, these forming only 1.2 per cent of the total deaths. The twenty leading causes accounted for 91.8 per cent of all the deaths; these are shown in table 5.

Far outstanding on the list are diseases of the heart and coronary arteries, with 40.7 per cent of the total deaths. Next in rank are intracranial lesions of vascular origin, accounting for 10.8 per cent of the deaths. There follow, in turn, cancer with almost 10 per cent, nephritis 6 per cent, pneumonia and influenza 5.5 per cent, accidents with almost 5 per cent, then arteriosclerosis, diabetes and suicide, each with about 2 per cent. Tuberculosis accounts for about 1.5 per cent of all deaths, and cirrhosis of the liver for a somewhat smaller proportion. The proportion for each of the remaining causes on the list is less than 1 per cent.

DEATH RATES BY CAUSE FOR PHYSICIANS AND GENERAL POPULATION COMPARED

It may be generalized that, on the whole, male physicians have higher death rates from the degenerative conditions than white males in the population but much lower death rates from most infectious diseases and surgical conditions.

---

[4] To insure comparability in the two experiences, the death rates for males in the general population were adjusted on the basis of the age distribution of male physicians in 1940. The age adjusted death rates so computed show what the mortality of physicians would have been if they had experienced the age specific death rates (in five year age groups) of white males in the general population.

The greatest excess in the mortality of physicians is found from leukemia, their death rate from this cause being 175 per cent of that for white males in the general population (table 6). Some of this excess mortality among physicians undoubtedly reflects better diagnosis, but consideration has also been given lately to the possibility that in some instances the condition may have been induced by their exposure to x-rays.[5] Next in rank of excess mortality is biliary calculi and other diseases of the gallbladder, with a ratio of 145 per cent. The reason for this large excess is not apparent, but it too may arise from better diagnosis. Fortunately, the death rates from these two causes are at a relatively low level.

Then follow three degenerative conditions with high death rates; these causes are intracranial lesions of vascular origin, with a ratio of 120 per cent in the death rates of male physicians to white males of the same ages, arteriosclerosis with a ratio of 116 per cent and diseases of the heart and coronary arteries with 118 per cent.

If the recorded death rates from diseases of the coronary arteries are considered alone, the ratio of the mortality of physicians to that of white males generally reaches the high figure of 181 per cent. Two important considerations arise in this connection. First, coronary disease may be expected to be recorded more frequently as a cause of death among physicians than among the general population simply because of the better opportunities for accurate diagnosis in this profession. Then in some instances where the death certificate was not available, diseases of the coronary arteries may be reported incorrectly or without mention of the contributing causes.

However, it appears unlikely that the foregoing reservations are sufficient to account for the entire excess mortality from diseases of the coronary arteries among physicians. If coronary disease was given undue emphasis in reporting causes of death, it was quite likely done at the expense of the other diseases of the cardiovascular-renal system. In this circumstance one would expect that the death rate from the cardiovascular-renal group, excluding coronary arteries, would be lower for physicians than for white males generally. This, however, is not the case in the present experience. The detailed data of table 7 show that at ages 35 to 44 [illegible] death rates from the cardiovascular-renal diseases, [illegible] those of the coronary arteries, are at the [illegible] for physicians and white males generally; at [illegible] to 64, physicians actually have the higher death rates by a good margin. The suggestion remains, therefore, that the higher death rates from diseases of the coronary arteries among physicians than among white males generally may not arise entirely from better diagnosis and reporting but that causative factors may be present. Although there have been some opinions to the contrary,[6] the results of Smith from records of the Mayo Clinic[7] are pertinent in this connection. Six

occupational groups were studied in which all cases were subject to the same criteria for diagnosis. In each age group the proportion of cases with coronary sclerosis was found to be much higher for physicians than for the other occupations.

There are left four causes on the list with death rates for physicians above those for white males generally. For two of these, cirrhosis of the liver and diabetes, the excess may reflect, largely, better diagnosis and reporting. It is pertinent to note at this point that a study of Joslin's records shows that diabetic physicians experience lower death rates from all causes than do persons with diabetes generally;[8] this may be a result of their advantages for early diagnosis and better treatment. As for the small excess mortality from suicide among physicians, a similar finding has been observed in other experiences. Among all the causes of death for which physicians have the higher mortality, there is only one infectious in nature—pneumonia and influenza. The excess mortality here is 9 per cent, and most of it is due to the high death rates from these conditions among physicians at 65 and over.

* The general population death rates have been adjusted on the basis of the age distribution of male physicians in 1940

For the only other two infectious conditions among the leading causes of death, namely tuberculosis and syphilis, the death rates for physicians are very low as compared with white males generally. In the case of tuberculosis the physicians have less than half the general death rate, while for syphilis it is only one third. The more favorable mortality among physicians from these two conditions reflects largely the better situation in the social-economic class to which they belong and also the self selection by the healthier lives to study medicine. In addition, where physicians are exposed to infections they have the advantages of better knowledge of how to protect themselves and to control infections that have been acquired. The mortality from nephritis among physicians was only 73 per cent of that for white males generally. The full significance of this better showing is not apparent. The explanation may be, to some extent, in the quality of the reports of causes of death.

Aside from these three conditions—nephritis, tuberculosis and syphilis—the other diseases for which physicians experience the more favorable mortality are generally amenable to surgical intervention. These include cancer, with a ratio of 81 per cent in the death rates of male physicians to white males, appendicitis with 77 per cent, hernia and intestinal obstruction 75 per cent, ulcer of the stomach or duodenum 62 per cent and diseases of the prostate 54 per cent. The advantage of physicians from these conditions as compared with the general population is probably due to their appreciation of the significance of symptoms and their better opportunities for early diagnosis and also for prompt and expert treatment.

Another indication of the precautions exercised by physicians, as far as the obvious hazards are concerned, is found in the low incidence of fatal accidents among them as compared with white males in the general population. Their death rate from automobile accidents was 89 per cent of that for the general population, while the ratio for all other forms of accidents was only 60 per cent.

CONCLUSION

The overall picture is that physicians experience practically the same longevity and mortality as white males of the same ages in the general population. According to data for the period 1938-1942 the average length of life for the young man entering the medical profession at age 25 is forty-three and a half years; for the young woman at 25 it is over forty-seven years. The mortality among male physicians is at a rate of 2 per cent per annum.

The physician, utilizing his special knowledge and skills, profits from the early recognition of the immediate conditions and hazards which affect his health. Evidence in this direction is found in the favorable mortality from most infectious diseases and surgical conditions and from accidents. The death rate from tuberculosis among male physicians is less than half that of white males of the same ages in the general population; for syphilis the ratio is only one third. The death rate from cancer among male physicians is four fifths of that for white males of the same ages; in the case of appendicitis, hernia and intestinal obstruction the ratio is three fourths. Fatalities from automobile accidents among male physicians occur at a rate nine tenths of that for white males generally; for all other types of accidents the ratio is only three fifths.

These advantages are offset by a relatively high mortality from the cardiovascular conditions. In particular, the recorded death rate from diseases of the coronary arteries among male physicians is one and four-fifths times that of white males of the same ages in the general population. This excess cannot be accounted for entirely by better diagnosis and by the quality of the reporting of causes of death; it is suggested that causative factors may be present in the higher mortality from diseases of the coronary arteries among physicians The causes are not immediately apparent, and there is therefore much room for surmise. There come to mind the special activities and burdens of the profession: their call to service at any time, their constant guard against varied infections and their need for mental alertness all may well impose strains that are felt in few other callings.

---

[8] Diabetes in the 1940's, George F. Baker Clinic, Boston and Metropolitan Life Insurance Company, New York, September 1940.

The mortality from leukemia among male physicians is one and three-fourths times that of white males generally. Although better diagnosis may account for some of this excess, opinion has been expressed recently that in some instances physicians may have acquired the disease as a result of their exposure to x-rays.

There is room for much intensive study for underlying factors in the case of those conditions for which physicians experience a higher mortality than the general population.

ABSTRACT OF DISCUSSION

Dr. Haven Emerson, New York: While my studies of 1926, though less complete than Dr. Dublin's of today, showed essentially the same characteristic, may I be permitted to doubt the assumption offered this morning to the effect that "knowledge of the causes of death of physicians may well point the way to effective preventive measures." Not unless we have some rational inkling of the predisposing and precipitating etiology and find them to be preventable. The main cause, I believe, of this high rate among certain causes of death is that we are entirely, as a profession, whether a public health profession or a medical profession, wholly ignorant of the determining and predisposing factors that lead to these deaths from the cardiovascular-renal complex. We really know nothing useful as to the causative or preventive factors that lead to cardiovascular deaths in physicians or others in the decades above 60 years. Work, anxiety, sustained mental alertness, irregularity of rest, food and exercise are common to many others than physicians. Leukemia as a preponderant cause should prove possible of occupational explanation. What seems to me well maintained in the present and other studies of deaths of physicians is that where a cause is known, and known to be preventable, physicians take the benefit of this knowledge and put it to personal use earlier than they can make it effective among their patients, or at least than it can be demonstrated in the general population. Other things being equal, the higher the cardiovascular death rate in the community, age, sex, race and occupation being considered, the better has been the public health service in that community. I see no reason to believe that the high rates for these conditions among physicians means anything more than that physicians have, on the whole, been spared more commonly to live into the decades when nature takes their fate in hand and cuts the thread of life. There is little evidence that physicians as a class observe the precaution of periodic health examination, endorsed by the A. M. A. as long ago as 1922, nor is there any evidence of superiority of general hygienic practices by physicians, especially in matters of diet and habitual use of alcohol, and tobacco particularly. I should say that we have not proved any point of superiority of physicians in the manner of their living, although there is probably for the medical student a more thoughtful regard for his health through the use of repeated chest x-ray examinations particularly than for other persons likely to be separately recorded. I think we must learn more of functional pathology and the problems of metabolism, the natural history of aging, rather than to rely on comparison between physicians and the general public as evidence or explanation of differential death rates of physicians.

Dr. Louis I. Dublin, New York: I would go along with Dr. Emerson if what I showed with regard to the excess mortality from coronary disease were limited to the age period 65 and over. There would then be merit to his point, and we wouldn't have made the statement he quoted. However, these excesses in mortality from coronary disease amount to 44 per cent at ages 25 to 44 and to 88 per cent at ages 45 to 64. Such excesses in mortality at relatively early ages do not indicate that we are concerned with the inevitable and that, since death is our lot, coronary disease and heart conditions must loom large in the picture. We know that advantage can be taken of existing knowledge in the fields of medicine and public health; for the preventable diseases have already been very much brought under control. Dr. Emerson would suggest that we really know next to nothing with regard to the preventability of the cardiovascular conditions. That doesn't seem to fit at all into what we, as public health people, are insisting in all our public statements. What is the basis of the entire campaign in the heart field and in the field of personal hygiene? Does the physician help himself? Does he follow what he knows and what he tells his patients? Dr. Emerson himself later indicated that there was a good deal of merit in the criticism that the doctor himself doesn't follow his own mandate with regard to diet, with regard to rest and with regard to exercise. The point that he made with regard to the high mortality from cardiovascular disease in those communities which have the lowest death rates and the highest sanitary standards has no bearing here. I know perfectly well that lives are saved from typhoid, tuberculosis and diphtheria, so that an increasing proportion of deaths will occur at the higher ages. By the end of the century 90 per cent of all deaths will be beyond age 45. But that is not what we are talking about; we are concerned with comparisons of mortality made age for age. I showed you the real advantages which the doctor has in mortality from most infectious diseases and from surgical conditions. But against these advantages are the evidences of some faults in personal hygiene and of a very difficult way of life. This helps explain what we have shown. One would have every right to believe that for a group of physicians beginning their career about age 25 there would be an advantage of a number of years in expectation of life as compared with the general population at the same stage of life. But the advantage doesn't exist; it has been washed away. Whatever they have saved from some infectious and surgical conditions they have lost by not making the most out of the advantages that come from a good personal hygiene and normal tempo of living.

MEAT IN THE DIET OF YOUNG INFANTS

RUTH M. LEVERTON, Ph.D.
Lincoln, Neb.
and
GEORGE CLARK, M.D.
Omaha

The use of meat in the diet of infants before the age of 6 to 9 months has not been a general practice, because of the prejudice that meat is hard to digest and because it has not been available in a suitably homogeneous form. With scientific evidence to refute the prejudice and with commercially strained meat now available for use, meat presents itself to the pediatrician and parent as a concentrated source of high quality protein for supplemental feeding at an age when the protein requirement, expressed on the basis of body weight, is at its highest.

Reported here are the results of adding strained meats to the formulas of bottle-fed babies beginning at the age of 6 weeks and continuing for a period of eight weeks. The purpose was twofold: first, to determine the acceptability of and tolerance for meat in infants at an early age; and second, to determine the effect on the hemoglobin and red cell values in infants receiving meat as compared with those receiving no meat. The work was done in two institutions in which normal well babies were kept pending their adoption or their return to parental homes.[1] During a six month

[1] The staff members of the two institutions cooperated in this study.

d 33 infants were studied; 18 received the strained t supplement and 15 served as controls.

The strained meat was mixed with the formula just before it was distributed into the bottles for individual feedings. The amount of meat added was determined by calculating the quantity necessary to increase the protein content of each infant's formula 25 per cent, and therefore it varied with the strength of the formula and the variety of meat used. The varieties were veal, beef, pork and lamb; one was used each week, and then the sequence was repeated. The amount of strained meat averaged about 27 Gm. daily. The total amount was not added abruptly—one third of the total was added for three days, this was increased to two thirds for the second three days, and then the full amount was added beginning the seventh day. The "dextri-maltose" in the formula was decreased sufficiently to compensate for the calories furnished by the meat.

One institution used fresh milk and "dextri-maltose" for the formulas and gave each infant a 25 mg. ascorbic acid tablet daily. The other institution used evaporated milk and "dextri-maltose" and used tomato or citrus fruit juice as a source of ascorbic acid. Both institutions used a concentrated source of vitamin D. All the babies were given five feedings at four hour intervals omitting the 2 a. m. feeding.

Comparison of Blood Values of Meat Group and Control Group of Infants

	No	Age of Infants 6 Wk	12 Wk	14 Wk
Actual				
Hemoglobin, Gm /100 cc				
Meat group . ..	18	10.5	11.5	11.9
Control group	15	10.7	10.3	9.6
Red cells, m /c mm				
Meat group	18	3.60	4.13	4.40
Control group	15	3.67	3.87	3.90
Percentage of initial value				
Hemoglobin, Gm /100 cc.				
Meat group . ..	18	100	109.5	113.3
Control group ...	15	100	96.3	89.7
Red cells, m /c mm				
Meat group	18	100	114.7	122.2
Control group	15	100	105.4	106.2

Records were kept of the number, color and consistency of the stools, of daily temperature, food intake and regurgitation, and of comments from the members of the nursing staff in regard to the infants. The infants were weighed three times a week and measured at the beginning and end of the study.

At the beginning of the study, when each infant was 6 weeks old, the hemoglobin and red cell content of the blood was determined. Hemoglobin was converted to acid hematin and read in a Cenco-Sheard-Sanford photelometer. The blood tests were repeated at the end of six and eight weeks, or when the infants were 12 and 14 weeks of age.

RESULTS

The infants readily accepted the formula with the strained meat added and demonstrated no distress from it. During the first week on the strained meat supplement 10 of the 18 infants averaged one more stool a day than during the week previous to the addition of meat or during the second week of their meat regimen. As was to be expected, over the short period of eight weeks there was no difference in the gain in weight or length of the infants receiving the strained meat as compared with the controls. The nurses considered that in general the babies who received strained meat routinely were more satisfied and slept better at night than did the control babies. The pediatrician (G. C.) in charge of the medical care for all the children considered that the babies were in a better physical condition as a result of receiving the meat supplement.

The results of the blood tests are shown in the accompanying table. The values determined six and eight weeks after the initial test are expressed in percentage of the initial value. In this way each infant is compared with himself, and his progress is indicated by values above or below 100 per cent.

It may be seen that the average hemoglobin and red blood cell values of the 18 infants who received meat for eight weeks were 113.3 per cent and 122.2 per cent, respectively, of the average values at the beginning of the study. Similar comparison of values for the control group shows that the hemoglobin and red cell content was 89.7 per cent and 106.2 per cent of the initial values. There was less variability as judged by the range of individual values in the meat group than in the control group.

On the basis of these figures it appears that the addition of strained meat to the formula not only checks the drop in hemoglobin characteristic of this age but actually promotes the formation of hemoglobin and red blood cells. It is not within the scope of this preliminary study to speculate on which factor or factors in the meat were responsible for the improvement. From the practical point of view, meat is a food, and this food made the difference in the supplemented group as compared with the control group.

SUMMARY AND CONCLUSIONS

1. No adverse symptoms occurred when the protein intake of 18 bottle-fed infants was increased by 25 per cent by the addition of approximately 1 ounce (27 Gm.) of strained meat to the formula when the infants were 6 weeks of age.

2. The observations of the pediatrician and the members of the nursing staff suggest that the general well-being of the infants who received the meat supplement was better than of the controls.

3. This preliminary study indicates that strained meat added to the formula of bottle-fed infants not only checks the drop in the hemoglobin level, which is characteristic of this age, but actually promotes the formation of hemoglobin and red blood cells.

Coronary Subsidiary Channels.—In later years it has become well known that there is a rich network of anastomoses which runs throughout the muscle and connects terminals not only from neighboring small branches but even from the right and the left coronary. It now appears that, instead of increasing the number in later years, nature laid them down to begin with —many tiny communicating filaments with little to do but be ready when called on. If there is any interference with arterial flow in one locality, an inflow of blood is sent from less obstructed territory through these subsidiary channels, which enlarge with use. . . . Coronary disease of extent sufficient to produce angina is a serious matter. Sudden death may occur. Complete occlusion with or without myocardial infarction may ensue. Congestive failure may follow. In many instances the development of collaterals, the avoidance of precipitating factors and the relief of accompanying disturbances may result in temporary or permanent cessation of attacks, the disease then becoming latent. In many cases proper attention to abdominal symptoms yields valuable results. And equally if not more important, the patient should have the confident assurance from his doctor that nature, continually at work to develop an adequate collateral circulation, may count him among her successes. —Luten, Drew W.: The Clinical Course of Coronary Disease, *Postgraduate Medicine*, May 1947.

HISTOPLASMOSIS

A Review of the Cutaneous and Adjacent Mucous Membrane Manifestations with a Report of Three Cases

ARTHUR C. CURTIS, M.D.
Ann Arbor, Mich.
and
JOHN H. GREKIN, M.D.
United States Public Health Service

Histoplasmosis has been considered, until recently, an extremely rare disease of tropical origin, but in the current literature there has been a geometric increase of case reports. Most cases of histoplasmosis have been systemic and generalized, but involvement of the skin and nearby mucous membrane is common, and there is evidence that the disease may be local as well as generalized.

Darling[1] described the first 3 cases of histoplasmosis in Panama; hence the tropical connotation long attached to the disease. He did not suspect that the etiologic agent was a fungus but believed the organism to be protozoan in nature. Da Rocha-Lima,[2] who studied Darling's microscopic sections in 1913, was the first to suggest a yeastlike fungus as the cause of the disease; but confirmation of the correct etiology was not forthcoming until 1934, when De Monbreun[3] cultured the fungus from the blood and spleen of an infant 5 months of age and suggested its identity with the organism observed in the original cases.

From the time when Darling described the disease until 1937, only 13 valid cases were recognized, and 6 of these were identified in retrospect. Almost 70 cases have been described in the past eight years, and many of these have had primary or secondary extensions pertaining to the skin. The realization that diagnosis often depends on a prolonged and painstaking microscopic search for the organism by a trained pathologist has led to more frequent recognition of the disease.

MYCOLOGY

Histoplasma capsulatum is different from other pathogenic fungi in that it primarily invades the reticuloendothelial system; hence, the synonym for histoplasmosis is reticuloendothelial cytomycosis. The organism occurs in tissue intracellularly in the macrophages as a small round encapsulated yeastlike body, with the capsule easily discernible. According to Parsons and Zarafonetis[4] it varies in size from 1 to 5 microns with an average diameter of 3 microns, although larger forms up to 10 microns have been recognized. The microscopic differentiation of H. capsulatum from the organisms of leishmaniasis and toxoplasmosis is important. The tissue pathology is that of a granuloma with pseudotubercle formation, necrotic foci bordered by macrophages containing the organism and areas of ulceration (fig. 1).

Direct identification of the organism can sometimes be made from smears of the peripheral blood,[4] of material from sternal aspiration and of material from fresh biopsy specimens (fig. 2). As reported in our first case, the fungus was found in a specimen of sputum. Occasionally, budding forms are seen in fresh preparations. Hematoxylin and eosin, Giemsa and Wright's stains are among those more satisfactory for use in both biopsy material and direct smears.

At room temperature, H. capsulatum grows on Sabouraud's medium as a white, fluffy, aerial mycelium which is grossly indistinguishable from Blastomyces dermatitidis (fig. 3). It has been an observation of ours that it cracks the medium somewhat as does Paracoccidioides cerebriformis (fig. 4). In culture mounts from young colonies both H. capsulatum and B. dermatitidis show septate and branched hyphae bearing small pyriform or round spores 2.5 to 3 microns in diameter (fig. 5). As the cultures of H. capsulatum grow older, however, a microscopic mount will reveal characteristic tuberculate chlamydospores. These are large spores 7.5 to 15 microns in diameter with easily discernible spiny processes projecting from the entire surface. Their presence establishes the diagnosis (fig. 6). At 37 C. on blood agar the organism grows as a yeast in moist white colonies, which reveal on culture mounts a tiny budding yeast body varying in size from 1 to 5 microns and similar to the forms found in tissue. Biopsy specimens, peripheral blood, material from sternal aspiration and abscess fluid should all be cultured.

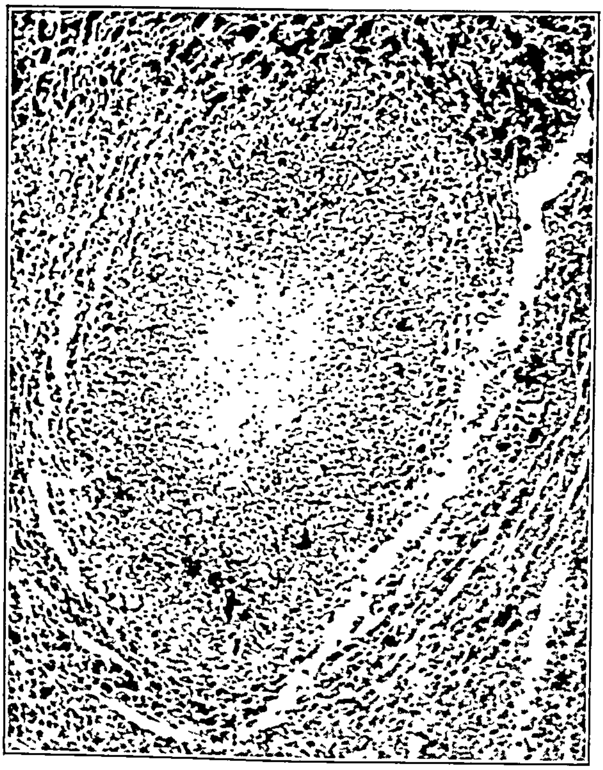

Fig. 1.—Low power photomicrograph of a section of adrenal gland with a typical lesion of histoplasmosis. Pseudotubercle formation within the granulomatous mass is apparent.

A third method of diagnosis which has attained an equivocal degree of success is the skin test, developed independently by Van Pernis, Benson and Hollinger[5] and by Zarafonetis and Lindberg.[6] The antigen, known as histoplasmin, consists of a sterile filtrate prepared from broth cultures of the organism and is injected intracutaneously, the test being read after forty-eight hours. Positive reactions present both edema and erythema, the former having a diameter of at least 5 mm.

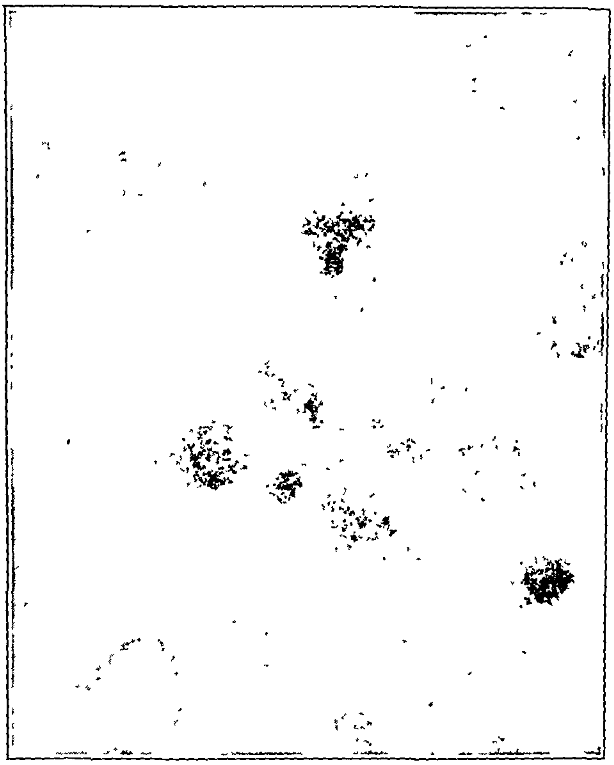

Fig. 2 (case *2*).—Photomicrograph made from microscopic section of the lesion of the tongue. An abundance of H. capsulatum organisms is visible within the macrophages (oil immersion).

Specificity of the test has been studied by several investigators. Emmons[7] found that of 39 guinea pigs infected with experimental histoplasmosis, 32 reacted to histoplasmin, while all of 8 experimentally infected with blastomycosis reacted to histoplasmin. After delving further into the problem as it concerned human subjects, Emmons expressed the belief that a positive reaction to histoplasmin might be due to sensitization either to H. capsulatum, B. dermatitidis or even to other as yet undetermined antigenic agents. Palmer,[8] after an extensive study of nontuberculous pulmonary calcification in student nurses, was of the opinion that positive reactions to histoplasmin should be regarded as evidence of previous infection with H. capsulatum or an immunologically related organism. He summarized the results of his investigation with the rather startling conclusion that a high percentage of pulmonary calcifications in persons presenting negative reactions to tuberculin were in his opinion associated with infections due to H. capsulatum. It was suggested by Christie and Peterson[9] that since the causative organism of histoplasmosis appears to flourish only in the yeast form in infected animals and human beings, an *antigen extract of this phase might logically be expected* to give more satisfactory results than the broth filtrate, with its extraneous antigens. Preparation of such a product would apparently require the use of a blood agar medium, with frequent transfers to fresh mediums.

The concept of subclinical varieties of histoplasmosis, in contrast to the severe, usually fatal form of the disease hitherto diagnosed, has been postulated by numerous investigators as an explanation for the high percentage of persons demonstrating a positive skin test with no detectable evidence of the disease in an active form.

In essence a positive cutaneous response to histoplasmin is frequently, for reasons cited previously, of little or no clinical significance, while a negative reaction may be helpful so far as it eliminates histoplasmosis as a diagnostic possibility.[9]

Various laboratory animals have been found susceptible to H. capsulatum, including mice,[5] rabbits,[6] rats[10] and guinea pigs.[11] This susceptibility can be a definite aid in the identification of the organism and diagnosis of the disease. De Monbreun[12] has reported the only case of the natural invasion of H. capsulatum in an animal, having isolated the organism from a dog.

of the reported cases [4] reveals the involvement of almost every organ. Darling [1] considered that the primary symptoms were fever, splenomegaly, loss of weight, anemia and leukopenia and that the disease was chronic in nature. The more commonly involved sites include the skin and adjacent mucous membranes, the larynx, lungs, liver, spleen and gastrointestinal tract, as well as the bone marrow and lymph nodes.

Three cases are reported here, each of definite diagnostic interest to the dermatologist, followed by a review of previously reported cases involving the skin or adjacent mucous membranes. Case 1 is also being reported elsewhere but is included because of the interesting cutaneous lesions and the problem in differential diagnosis. Material from the patients in cases 2 and 3 has been used in various in vitro tests of proposed therapeutic agents.[13]

REPORT OF CASES

Case 1.—F. F., a white woman aged 30, a native of Michigan, had been well until June 1943, when there suddenly developed a swelling in the right lower quadrant of her abdomen, which was soft, tender and associated with an erythema and an increase in the temperature of the overlying skin. No constitutional reaction was present, and the appendix and right ovarian tube of the patient were removed. Ten days later there developed pain in the left side and a bilateral thrombophlebitis, which was treated with a sulfonamide drug and healed in six weeks. She remained well until November 1943, at which time a swelling developed in the right cervical region which was painful and hot with reddish purple discoloration of the skin. It gradually enlarged to the size of a hen's egg and was associated with daily afternoon elevations of temperature to 102 F. and occasional sweats at night. The nodule was incised in December 1943. It exuded a watery yellow fluid, and drainage continued until August 1944, when closure finally occurred. From October 1943 until February 1944 the patient suffered from an irritating nonproductive cough. In January 1944 the spleen and liver were observed to be enlarged, and a nodule developed on the right wrist. This was incised in May 1944, discharging a yellow sanguineous fluid, and at the same time the patient received 1 million units of penicillin, after which the second lesion healed. However, two weeks later nodules developed on the forehead, the left leg, the left thigh and two on the right leg. These lesions ulcerated and drained, and while those on the left leg healed in several months, the others persisted. Splenomegaly, hepatomegaly and elevations in temperature continued to be present. There was nothing contributory in the family, social or past histories.

She was admitted to the University Hospital on Sept. 9, 1944, at which time physical examination revealed a chronically ill, pale and emaciated white woman. The temperature was 100 F., the pulse rate 100, the respiratory rate 20, the blood pressure 95 systolic and 60 diastolic and the weight 99 pounds (45 Kg.). The skin was dry and showed evidence of recent loss in weight. Two draining granulomatous lesions were present on the right calf. These were fairly deep seated, soft, brownish purple and each about 2 cm. in diameter (figs 3 and 4). A fluctuant brownish purple nodule 1.5 cm. in diameter was present on the midforehead. Firm, nontender, hypertrophic brown scars, which varied from 1.5 to 4 cm. in diameter, were noted on the left calf, the left thigh, the volar surface of the right wrist and below the mandible on the right side of the neck. Significant involvement of the lymph glands was not present. The nasal mucosa was hyperemic, but the buccal mucosa was normal. The right side of the chest was dull anteriorly and over the axillary third and fourth intercostal spaces. Bronchovesicular breathing and coarse rales were present in these areas. Rales were also present at both pulmonary bases, and bronchial breathing was heard over the right base. The spleen was palpable 2.5 cm. below the left costal margin, moved freely with respiration and was nontender. The liver was palpable 3 cm. below the costal margin at the right nipple line and 6 cm. below the xyphoid cartilage and was slightly tender. There was decided tenderness over the right hip joint with sciatic radiation. The deep tendon reflexes were not elicited in the lower extremities.

On the patient's first admission she remained hospitalized until November 1944. The diagnosis of histoplasmosis was made from the sputum examination, and while awaiting the arrival of an antimony compound for treatment the patient was placed on penicillin therapy, receiving 480,000 units daily. The course was progressively bad, and respirations ceased five days later. On the last day of life the liver and spleen were no longer palpable.

Urinalyses were persistently negative. Roentgenograms of the chest showed right hilar adenopathy and patchy pneumonitis of the right lung and atelectasis. Roentgenograms showed little change until February 1945, when widely disseminated parenchymal disease of both lungs was apparent, with patchy increase in density from apexes to bases bilaterally.

The total serum protein was 6.7 Gm. per hundred cubic centimeters on admission, with an albumin-globulin ratio of 2.2. The sulfobromophthalein sodium test for liver function showed 40 per cent retention of the dye by the liver in thirty minutes. The prothrombin time was 115 seconds as compared with a control time of 40 seconds. The congo red test for amyloid showed no retention of the dye in the tissues after one hour.

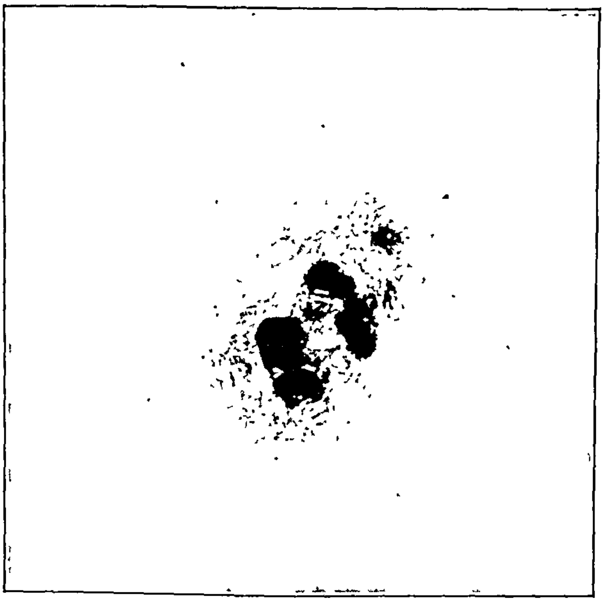

Fig. 8.—Close up view showing the upper of the two lesions in figure 7. This lesion was approximately 2 cm. in diameter.

The intradermal tuberculin test using a 1:10,000 dilution of old tuberculin was positive at twenty-four, forty-eight and seventy-two hours, showing an area of erythema and induration of 1 by 1.5 cm. The intradermal test for histoplasmosis was also positive, showing an area of erythema and induration measuring 2 by 2.5 cm. at twenty-four hours, 2 by 3 cm. at forty-eight hours and 3 by 5 cm. at seventy-two hours.

Repeated direct examinations of material from the cutaneous lesions, sputum and stool were negative for mycotic or tuberculous organisms until February 1945, when H. capsulatum was found in the sputum.

Antemortem biopsies from the cutaneous lesions on the leg, thigh and forehead revealed in each instance a chronic infectious granuloma with epithelioid cells about caseous centers, a round cell infiltrate and a few giant cells. In no instance were the organisms of H. capsulatum found, and repeated special stains for Mycobacterium tuberculosis were negative.

The pertinent autopsy observations were as follows: Grossly there were bilateral confluent necrotizing pneumonia, extensive granulomatous peritonitis with tubercle-like lesions and abscesses, extensive liquefying lesions in the liver and abdominal lymph nodes and miliary lesions in the brain, spleen, liver, thyroid, capsule of the pituitary body, adrenals, kidneys and urinary bladder. In addition there were a chronic adhesive pleuritis and an old fibrocalcareous tuberculosis of the right upper pulmonary lobe. Microscopically H. capsulatum was present in enormous numbers in granulomatous foci and in Langhans' giant cells in the lungs and spleen. The organisms were also identified in the brain, the walls of the large intestine, the abdominal lymph nodes, the bone marrow and the fallopian tubes The typical lesion was one of central caseation surrounded by an epithelioid zone and Langhans' giant cells. Tubercles and Myco tuberculosis were demonstrated in the liver.

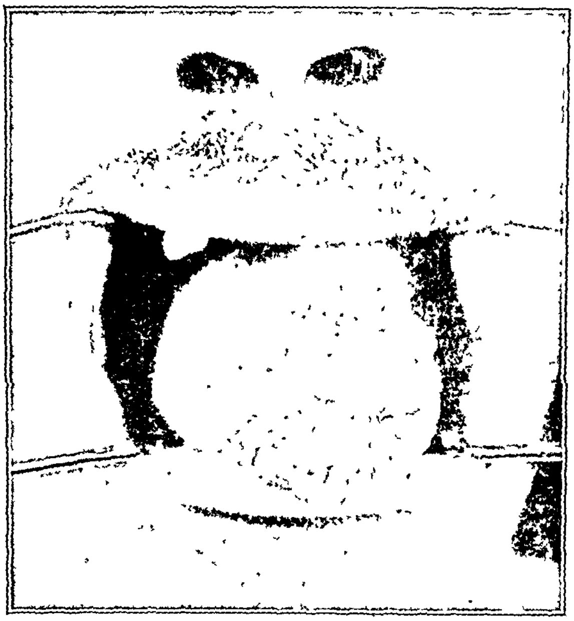

Fig 9 (case 2)—Involvement of the left side of the tongue by a large, firm, fungating lesion. The papular eruption over the chin had already cleared at the time this photograph was made

Case 2—I. T. W., a Negro man aged 42, gave a history of red, painful and tender nodules occurring about the scalp and neck in 1930. These lesions, which ulcerated and discharged a foul blood-tinged material, persisted over a period of several months, during which time the patient felt ill After this he was well until January 1944 when painful, swollen glands appeared in the left side of the neck just beneath the ear and progressively spread down the posterior cervical chain. This was accompanied by malaise, night sweats and some loss of weight. The glands were incised in March 1944, exuding a sanguineous material, and the discharge persisted intermittently until July 1944. In May 1944 his tongue became red, tender and swollen to twice its normal size, and the patient noted a definite nodule on the left side of the tongue. Over the surface of the tongue were many small white spots which on healing left a small linear trench A sanguinopurulent discharge from the mouth was present, and the lingual lesion persisted until his admission to the University Hospital on Oct. 19, 1944. Two months prior to admission a pustular eruption had developed on the chin and a crusted lesion in the right nares. The patient had lost 20 pounds (9 Kg.).

On physical examination the patient did not appear acutely ill. The temperature was 98.6 F., the pulse rate 72, the respiratory rate 16 and the blood pressure 120 systolic and 80 diastolic. There was a crusted, fissured lesion involving the lateral mucous membrane of the right nares. Large firm papules 4 to 7 mm. in diameter, some with pustular or vesicular elements, were present over the chin. There was an incisional scar in the left lower cervical region, and the anterior cervical and submental lymph nodes on the left were enlarged and firm but not tender. On the left side of the tongue was a large fungating lesion, which measured 2.5 by 5 cm. (figs. 5 and 6). This lesion was firm, extremely tender and grooved from the impression of the teeth. It bled easily. The tongue was freely movable, and no other lesions were present on the buccal or pharyngeal mucosa. Indirect laryngoscopic examination revealed a nodule, believed to be cystic in nature, on the epiglottis. The patient was not hoarse, the liver and spleen were not palpable and the remainder of the examination revealed normal conditions.

Microscopic sections of the lesion on the tongue showed decided hyperplasia of the prickle cells with a heavy inflammatory infiltrate consisting mainly of plasma cells with some lymphocytes and eosinophils widely distributed throughout the lingual tissue. Repeated biopsies revealed a similar picture, and in the fourth specimen, taken Dec. 1, 1944, the yeastlike organisms of H. capsulatum were identified intracellularly. Monthly biopsies thereafter in every instance revealed the organism, although by Feb. 28, 1945, at which time the last specimen was obtained, the tongue was essentially normal.

After the diagnosis had finally been made, on Dec. 22, 1944, the patient was given sulfadiazine orally and received 6 Gm. a day until March 27, 1945, a total dose of 576 Gm. No reaction to the drug was perceived. The course of the disease was one of steady clinical remission. The cutaneous lesions cleared in several weeks after sulfadiazine therapy was instituted, and by the early part of January 1945 definite improvement was noted in the tongue By February 1945 the tongue was normal in appearance, and the patient felt no pain or other symptoms. Nevertheless, treatment was continued until the end of March 1945, at which time he was discharged but advised to continue taking sulfadiazine and to return in four weeks Thus far he has not returned to the clinic.

Case 3.—C. W., a Negro man aged 23, had been well until February 1942, when a penile sore developed. The only symptoms were a loss of 10 pounds (4.5 Kg.) in weight and occasional discomfort at the site of the lesion. The patient was admitted to the Michigan Rapid Treatment Center[14] on March 6, 1945.

There was a fairly extensive ulceration of the prepuce with two round shallow ulcers, one at the anterior and one at the posterior border (fig. 7). Considerable erythema and erosion were present on the glans penis There was little tenderness and only a slight degree of induration. The inguinal lymph nodes were slightly enlarged bilaterally, discrete, not tender and of a rubbery consistency.

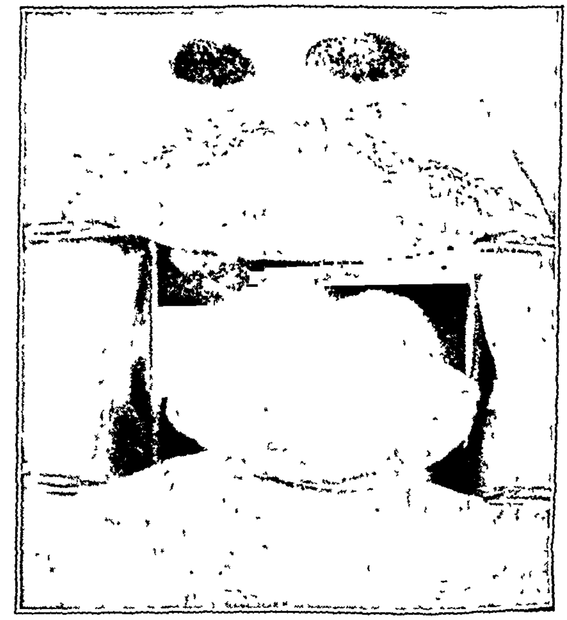

Fig. 10 (case 2).—Appearance of the tongue following the ingestion of 576 Gm of sulfadiazine over a period of approximately three months.

An intracutaneous test using a broth filtrate of a culture of H. capsulatum was negative after twenty-four, forty-eight and seventy-two hours. The test was later repeated with a different histoplasmin and was positive.

---

[14] Ryan, N. W., Medical Officer in Charge, Michigan Rapid Treatment Center, through whose courtesy this case report is included in this paper.

Biopsy material from the penile lesion revealed hyperplasia and ulceration of the epidermis. In the cutis at the base of the ulcer the sections showed a chronic infectious granuloma with an infiltration of lymphocytes and a few polymorphonuclear neutrophils, occasional giant cells and areas of caseation necrosis. With Giemsa stain the yeastlike form of H. capsulatum was identified in the reticuloendothelial cells. Similar microscopic observations were made in biopsy specimens from the inguinal lymph nodes, and H. capsulatum was again identified.

Cultures of material from the penile lesions on Sabouraud's medium at room temperature produced the characteristic white fluffy growth, and many tuberculate chlamydospores were found on culture mounts Blood agar cultures at 37. C. produced the budding form of the organism.

During the period of hospitalization, which extended over a span of approximately four months, a sharply circumscribed, brownish, pruritic papule, about the size of a half dollar, with a superimposed bulla, developed over the left palm (fig. 12). Cultures from and biopsy of this lesion did not reveal H. capsulatum, and within a few weeks it had cleared completely.

Treatment consisted initially of the intramuscular administration of 5.1 million units of penicillin in divided doses over a period of nineteen days. Subsequently the patient was given 522 Gm. of sulfadiazine during an interval of eighty-seven days. Several subsequent biopsies of the penile lesion were productive of only one alteration in the basic observations—the pathologist expressed the opinion that there appeared to be fewer organisms than in specimens obtained before treatment. At the last examination in April 1947, the penis was found to be enlarged because of a chronic lymphostasis In the areas of previous ulceration depigmentation was present, but there was no apparent clinical activity. A biopsy specimen did not contain demonstrable organisms of H. capsulatum.

The patient was released from the hospital to continue, under supervision of his local physician, the ingestion of 4.0 Gm. of sulfadiazine each day. At the last examination in April 1946 the disease process remained limited to the penis. The ulcers had healed The penis was enlarged because of a chronic lymphostasis. In the areas of previous ulceration depigmentation was present.

REVIEW OF THE CUTANEOUS LESIONS OF HISTOPLASMOSIS

In addition to the 3 cases reported in this paper 21 other cases presenting cutaneous lesions which were presumably associated with an infection of histoplasmosis have been reported (table 1). Histoplasma capsulatum was actually identified in the skin by microscopic section or by culture in 12 instances. Of the remaining 12 cases, 3 involved only purpura (cases 19, 20 and 21 in table 1); in 2 the description of the lesions was entirely inadequate (cases 1 and 4 in table 1); and 3 instances were most probably the cutaneous lesions of the complicating diseases (cases 10, 14 and 18 in table 1). One case (case 11 in table 1) presented a toxic erythema as the only cutaneous manifestation. The remaining 3 cases (cases 5, 22 and 23 in table 1) were probable or at least possible examples of cutaneous histoplasmosis, although the causative fungus was either not found or not searched for in tissue from the lesions of the skin. Of the 12 actual and 3 possible cases of cutaneous histoplasmosis, 13 had granulomatous or ulcerative type of lesions, 3 presented nodular lesions, 3 had papulonecrotic type of lesions, and 2 had abscesses. In 10 cases the cutaneous lesions were distributed over the face and neck, and in 6 of these they were directly adjacent to the orifices. Lesions were present on the trunk in 4 cases, on the extremities in 4 cases, on the male genitalia in 2 cases and were generalized in 1 case.

Considered in the differential diagnosis of the disease in the preceding 15 cases were gumma, primary syphilis, basal cell epithelioma, tuberculosis cutis, blastomycosis, chromoblastomycosis, granuloma inguinale and leishmaniasis.

REVIEW OF THE LESIONS OF THE MUCOUS MEMBRANE

In addition to case 2 of this paper we have found mentioned or described in the literature 23 cases of histoplasmosis in which involvement of those mucosal surfaces directly adjacent to the skin has occurred. In 7 of these 23 cases these lesions coexisted with cutaneous involvement and have been described previously in conjunction with the lesions of the skin (cases 4, 7, 15, 16, 18 and 20 in table 1).

A summary of the 24 cases with lesions of the mucous membrane reveals that the organism was actually recovered from the mucosal site in 17 instances and was found in directly adjacent cutaneous lesions in 1 case. Of the remaining 6 cases, 1 was definitely granulomatous and possibly of mycotic origin (case 4 in table 2); 1 was associated with erythema multiforme and clinically resembled a Vincent's angina (case 12 in table 2); 2 were associated with a coccogenic infection type of reaction (cases 19 and 20 in table 2), and 2 were merely cited and not described (cases 21 and 22 in table 2). This leaves for evaluation 1 probable and 18 definite cases of histoplasmosis of the mucous membranes adjacent to the skin. Of these 19 cases, 7 involved granulomatous lesions and 16 ulcerative lesions, which for the most part were painful. Nodular lesions ranging in size from several millimeters up to a walnut were described in 5 cases, and these were tender in 3 instances. Hemorrhagic patches or crusts of various sizes were noted in 4 cases; fissures were present in 2 cases and perforation of the nasal septum in 3 cases.

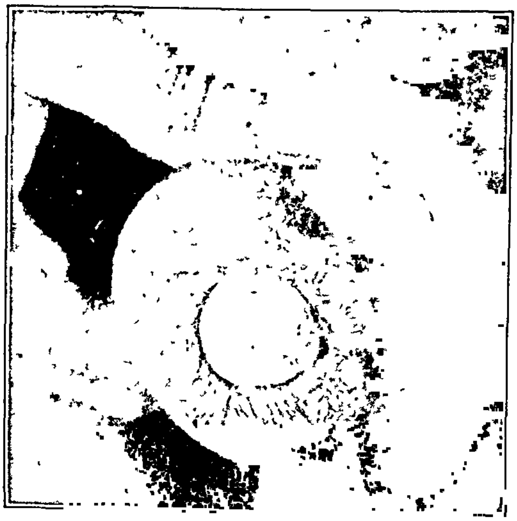

Fig 11 (case 3) —Ulcerations resembling syphilitic chancres at the anterior and posterior borders of the prepuce. There was moderate edema of the foreskin.

Lesions were present in the nose in 4 instances, on the tongue in 7, on the buccal and labial mucosae in 5, on the palate in 5, on the gingivae in 3 and about the hypopharynx in 7. Considered in the differential diagnosis were syphilis, carcinoma, leukemia, tuberculosis and leishmaniasis.

TREATMENT

Of the many agents used in the treatment of histoplasmosis, only antimony and sulfonamide compounds have thus far offered any encouragement in those cases in which progression beyond a purely localized involvement has occurred. Meleney[15] cites Mantel, Troy and Kendall, who treated a patient with histoplasmosis with an organic antimony compound[16] in the mistaken belief that they were dealing with an infection due to leishmania. The patient had a clinical remission while under treatment with this drug. Simson and Barnetson's[17] patient showed definite clinical improvement following the administration of an antimony compound, and as yet there has been no report of this patient's death. In the case of Palmer and others[18] the patient failed to tolerate an antimony compound[16] after the fifth injection. Several other cases[19] in which antimony compounds were unsuccessfully used have been recorded.

In case 2 of this paper the lesion of the tongue completely disappeared under continued sulfadiazine therapy, but even after a prolonged course of treatment microscopic sections still revealed H. capsulatum, and we have been unable to obtain the patient's readmission to the hospital. Other cases in which sulfonamide compounds, usually in small amounts, have been used unsuccessfully are reported.[20]

In case 3 the patient experienced healing of the penile ulcerations under sulfadiazine therapy. Repeated biopsies were all positive for H. capsulatum until April 1947, when all sections were negative. Chronic lymphedema and depigmented scars were residual. The patient appeared in good health when last seen, in April 1947.

Radium and roentgen therapy have been of value only in cases in which the lesion of histoplasmosis was entirely confined to a localized site. This is illustrated in the case cited by Parsons and Zarafonetis,[4] in which apparent cure was effected by radium therapy. Surgical intervention would probably have been equally effective in this case but was valueless in Moore and Jorstad's[21] case, in which wide excision was performed twice but further microscopic spread of the organism had undoubtedly occurred. In another instance[22] the local lesion of the tongue healed under radium therapy but the patient died several months later. No autopsy was performed, so the cause of death was not determined. In Humphrey's[19b] case temporary palliation was obtained from irradiation of the long bones, and in another case[19e] tenderness of the lingual lesion was temporarily alleviated following roentgen therapy. In another instance[4] roentgen radiation gave no relief.

COMMENT

At present the central portion of the United States appears to be the endemic focus of histoplasmosis. Parsons and Zarafonetis[4] have pointed out that 41 of the 71 cases reviewed by them were from this area, and 10 of these were from the state of Michigan. To these latter 10 cases may be added the 3 reported in this paper and 3 additional cases observed at the University Hospital which have not yet been reported.[23]

For the purpose of classification histoplasmosis may be divided into two categories. First, cases in which the portal of entry is primary in the skin and adjacent mucous membranes and second, those cases in which the portal of entry is a systemic one via the respiratory or gastrointestinal system and the cutaneous or mucosal lesions which do occur are from secondary invasion. Case 3 of this paper and the patient[4] whose lesion healed on radium therapy[4] are examples of the primary invasion, whereas case 1 of this paper and other cases[24] fall into the latter group and were the result of a hematogenous dissemination of the organism. However, except in those instances in which the lesion is so localized that complete extirpation will remove the disease, this classification is of far less prognostic significance than in blastomycosis. In the latter disease systemic invasion is usually fatal, but primary cutaneous blastomycosis may persist untreated for long periods of time and yet seldom causes death. In histoplasmosis any untreated lesion, whether primary or secondary, may go on to dissemination and finally a fatal termination, and the present methods of therapy have done little to improve this prognosis.

In addition to the actual invasion of the mucocutaneous tissues by H. capsulatum, the possibility of toxic and absorption type of cutaneous reactions must be considered. A toxic response to the systemic infection may well have been behind the purpuric, roseolar, vesicular and erythema-multiforme-like manifestations described in cases in which no organisms were recovered. In case 3 the patient had a fixed eruption on the left palm. However, the part played by drugs or other extraneous factors cannot be eliminated in several of these cases.

In differential diagnosis it is important to consider histoplasmosis in patients with anemia, leukopenia and fever, particularly if lymphadenopathy, splenomegaly or hepatomegaly are also present. No single symptom or group of mucocutaneous manifestations which are as yet apparent from the limited case reports would enable one to make a definite clinical diagnosis. The predominant lesion is an ulcerative granuloma which is usually covered by a crust, often painful and has little induration or peripheral inflammation. Neither the miliary tiny peripheral abscesses and sharply sloping vegetative border of blastomycosis nor the arcuate configuration of gummas are in evidence in most instances. Tuberculosis cutis must be differentiated from the papulonecrotic form of histoplasmosis, which in 1 case[19a] even presented apple-jelly nodules. Mucocutaneous leishmaniasis is perhaps the closest clinical entity to histoplasmosis, and here confusion of the two diseases in the laboratory is also a possibility. However, for the most part the geographic distribution of the two diseases has become quite different in the last few years. In Negroes lesions about the genitalia require differentiation of histoplasmosis from granuloma inguinale. Histoplasmosis is associated with regional adenitis, which helps to differentiate it from granuloma inguinale. As in case 3 of this paper, genital lesions of histoplasmosis may simulate a syphilitic chancre, but persistence of the lesion will differentiate the two.

It is of interest that in 2 instances[25] histoplasmosis was associated with leukemia and in 1 with Hodgkin's disease.[4] A clinical differentiation between leukemia cutis and histoplasmosis was difficult, and even though H. capsulatum was found in the lesions, they may have originally been leukemic in nature. Histoplasmosis, particularly of the tongue, has been confused in several instances with carcinoma. In far advanced cases, the immobilization of the tongue has not been noted in histoplasmosis.

Other diseases that must be considered in a complete differential list include moniliasis, tuberculosis cutis orificialis, rhinosporidiosis, lupus vulgaris, sporotrichosis and coccigenic abscess or impetigo in those few cases characterized by suppurative processes. In addition South American blastomycosis, oriental sore and other tropical diseases merit consideration. An unequivocal diagnosis on a clinical basis alone cannot be made, but it can be strongly suspected, and proof can be obtained by histologic study of the lesions and by cultures made from infected material.

ABSTRACT OF DISCUSSION

Dr. Carl W. Laymon, Minneapolis: As was pointed out, histoplasmosis is essentially a systemic disease. I think most dermatologists have had very little experience with it. Dr. Curtis' paper is especially valuable from the point of view of differential diagnosis. After his presentation, it is easy to understand that this disease can mimic many other dermatoses and diseases of the mucous membrane. Christie and Peterson, of Nashville, yesterday in the Section on Pediatrics presented a paper on this subject. They, too, stressed that in patients with pulmonary calcification who had negative tuberculin tests, there was a high incidence of positive reactions to the histoplasmin test, so that in all probability there may be a benign or attenuated form of this organism such as Dr. Fred Weidman mentioned in discussing Dr. John Lamb's paper. As Dr. Curtis mentioned, a lapse of several years (from 1906 to 1925) occurred between the original description by Darling of 3 cases and the fourth case. It just happened that this fourth case was reported by two men from the University of Minnesota, Drs. Watson and Riley. It is of interest that one of the early cases occurred in a leprous person and in all probability the portal of entry in that case was through a lepromatous nodule. Another point which is interesting to speculate about is that there are many more cases of histoplasmosis in adult males than in adult females. Some believe that probably the adult male contracts the organism outdoors and then tracks it through the house and in that way the children playing and crawling around on the floor may get the disease. It has occurred in infants and young children, but it is infrequent in women. In the patients below the age of 10, the sex ratio is about equal in contrast to a 5 to 1 ratio of males over females. Since the central part of the United States, and especially Michigan, seems to be an endemic focus of this disease, Dr. Curtis has had really an unusually wide experience with it, and we are all fortunate to hear the results of his studies and observations.

Dr. John F. Kessel, Los Angeles: Dr. Curtis' paper is an excellent summary of histoplasmosis, with special reference to involvement of the skin and mucous membranes of man. His differentiation of these types of histoplasmosis into primary and secondary brings this disease into line with other systemic mycotic infections; for example, (1) coccidioidomycosis, in which cutaneous lesions are usually secondary to the disseminated type of disease, but which also may occasionally be primary in nature; for instance, a case in Los Angeles some years ago, in which the local lesion was on the shoulder. After diagnosis, cauterization was performed and the patient had no further disturbance and (2) torulosis, in which the lesions most commonly observed are in the central nervous system, but in which occasional local lesions without involvement of the central nervous system have been reported; for instance, the case reported by Drs. John C. Wilson and F. M. McKeever in Los Angeles, in which there was an infection of the knee and also a cutaneous lesion near the nipple. Amputation of the leg just above the knee and local roentgen therapy of the lesion of the skin resulted in cure. Histoplasmosis possesses certain parallels with leishmaniasis, which also involves the reticuloendothelial system. In leishmaniasis several different strains or species of organism are recognized, such as Leishmania donovani of kala-azar, which is primarily a systemic infection, and Leishmania tropica of oriental sore, which is a cutaneous infection. It is possible that differences in strain likewise occur in the histoplasma. Studies which I have in progress with cryptococci, some isolated from lesions of the central nervous system and others from cutaneous lesions, indicate that differences between strains occur in this fungus. It is of special significance that primary cutaneous and mucosal histoplasmosis tends to become generalized more frequently than is the case in certain other mycotic infections, for example, blastomycosis. Three cases of histoplasmosis have been reported from the state of California. In the first case the patient had previously resided in Louisiana, in the second in Tennessee and in the third in the North Central United States. These observations support the impression that histoplasmosis is not indigenous to the Pacific Southwest. Of these 3 cases only in the third was there exhibited a mucosal lesion which involved the tongue. The question of the specificity of the histoplasmin test and its value in diagnosis or survey work is still open for study. The workers who have reported on this so far have all been careful investigators, and yet there is some difference of opinion among them.

Dr. Frances Keddie, San Francisco: I am sorry that Dr. Miller is not here to discuss this with you. He and I are interested in histoplasmosis because of the case we saw here in San Francisco. In going over the literature of the 88 cases we found reported, 45 patients had lesions on the skin or mucous membranes, and 28 of these had lesions on the tongue, on the oral mucosa, in the larynx or in the pharynx. These lesions began as papules and frequently went on to ulceration. These usually were not tender when they were papules but became tender when they ulcerated. Sometimes the process was extensive, and in those cases there was destruction of the larynx and of the pharynx. The lesions on the cutaneous surfaces were much like those in the mouth, in that they began as papules and frequently went on to ulceration, forming a sharply punched-out ulcer. In some instances these ulcers had been present from eight to sixteen years. Purpura was mentioned in a few instances. It was usually terminal and occurred principally in children. The lesions that interested us particularly were those which resembled secondary infection, such as impetigo, furuncles and abscesses. These were mentioned in 4 patients who had generalized histoplasmosis; it was not indicated whether the organism was recovered from these lesions that looked like secondary infection. In 4 instances there was dermatitis, either local or generalized, and in 1 case of Hansmann and Schenken a generalized dermatitis had been present for sixteen years. The diagnosis was made by a biopsy from the skin. I have been impressed in going over the literature that the diagnosis can be made by sections from the skin and by finding the organism present in those sections. The patient we saw was a problem. He had histoplasmosis of the tongue, which we diagnosed by biopsy. He had had a lymph node removed from his neck six years previously, which was diagnosed Hodgkin's disease, and in getting this section and going over it after we made our diagnosis, we were able to find a few cells that resembled histoplasma. We took an auxiliary lymph node and found histoplasma in that. The patient had fever and was emaciated. He was in the hospital. We assumed that his generalized infection was histoplasmosis, although we were never able to find histoplasma in the blood

or in bone marrow smears. We gave him penicillin and also sulfadiazine in large doses. We also treated him with stibamine glucoside ("neostam"). He died from what we thought was a terminal bronchial pneumonia. We discovered at autopsy that his histoplasmosis was probably of a benign form. He had no histoplasma present any other place in his body. He had Hodgkin's disease of the lymph nodes, a Hodgkin's sarcoma of the liver and of the spleen, and he had a miliary tuberculosis which had become disseminated. So it is easy to understand that our attempts at treating histoplasmosis had little effect.

Dr. Fred D. Weidman, Philadelphia: In addition to the intrinsic value of this paper I am sure that all of us have been delighted in its manner of presentation. It stimulated thought in many directions. The histologic sections of 1 of the cases demonstrated the presence of granulomas in the liver, which histologically appear to be those of tuberculosis. I wonder whether the patient had tuberculosis in addition to histoplasmosis. I think the time is ripe to advance the theory at least that preexisting, particularly granulomatous diseases, can act as predisposing factors for the superimposition of a fungous infection. Dr. Keddie has just cited such a case, in which Hodgkin's disease was associated with fungous infection in the tongue, and a number of years ago Dr. Fitchett and I reported a case of Hodgkin's disease in which torulosis was present. I wonder whether such a thesis could be reconciled with what is so notorious in immunologic tests for fungous disease, particularly the cutaneous reactions. In the literature time and time again cross reactions are reported between the tuberculin, coccidioidin, blastomycetin tests and so forth. Does this connote the presence of antigens common to Mycobacterium tuberculosis (or other micro-organisms) and the fungous agent, and does the antigen in the Myco. tuberculosis or other micro-organism sensitize the person, more easily furthering the development of a fungous infection? The second point I would like to raise—Dr. Kessel anticipated me—is the matter of the future development of the antigens for skin testing. It is remarkable that physicians have been confining themselves to the employment of material from cultures. Now, all are aware of the extreme dimorphism of the fungi; most of them appear different in the test tube than in tissues. This must connote a difference also in the physiology and, with that, the production of differing antigenic substances. Isn't it more reasonable to assume that the specific antigens in the case would be more faithfully represented in the tissue form of the parasite than in the culture tube form? This does not raise any serious difficulty; tissue forms can be obtained. In the lepromin and the Frei tests, for example, tissue is used, but the tissue forms of the fungi can be secured on blood agar in the incubator and also in the chick embryo. I would suggest that increasing attention be paid in this direction in further attempts to improve the specificity of immunologic tests for the fungi.

Dr. Harry L. Arnold, Honolulu, Hawaii: I would like to extend slightly Dr. Weidman's remarks on the question of depression of production of antigens by tuberculosis and subsequent infection with some other organism. It might be well to allude to another possible explanation of these relationships, namely, the involvement of the reticuloendothelial system, which must be considered whenever one is considering the production of antigen. It is notorious that in leprosy, which is, in lepromatous form at least, essentially a reticuloendothelial disease, tuberculosis has an extremely high incidence. About 50 per cent of patients with lepromatous leprosy contract, and die of, tuberculosis; and histoplasmosis is also a disease which essentially involves reticuloendothelial cells. Possibly in this disease, as perhaps also in leprosy, there is a blocking of the reticuloendothelial system with resultant increased susceptibility to another infection.

Dr. Louis A. Brunsting, Rochester, Minn.: This has been a stimulating discussion of a condition in which the skin reflects signs of systemic disease. I am sure that none is better qualified to do this than Dr. Curtis. Perhaps at the Centennial Program of the American Medical Association next year the Section on Dermatology may join one of its day's meetings with the Section on Internal Medicine or Pathology to present a symposium on the systemic aspects of cutaneous disease. The subjects of acute disseminate lupus erythematosus and sarcoidosis, among others, would lend themselves well to such a discussion. As Dr. Curtis pointed out, the early lesions of histoplasmosis may be visceral or may appear first on the skin or mucous membranes, and the differential diagnosis includes carcinoma, tuberculosis, sarcoidosis or rhinoscleroma. The first step toward a correct diagnois is to keep histoplasmosis in mind; repeated cultures and biopsies may be needed before the organism is identified. The histoplasmin skin test deserves a wider application than it has had in the past, particularly in unusual ulcerative processes of the mouth and nasopharynx. A positive or negative skin test should not be given too much weight by itself but should be interpreted in respect to the overall picture.

Dr. Arthur C. Curtis, Ann Arbor, Mich.: It is not my desire to leave the impression that the sulfonamide drugs are specific for histoplasmosis. The last 2 cases in our report were benign forms of histoplasmosis, but 2 cases of benign histoplasmosis showing evidence of healing under sulfadiazine therapy are not sufficient evidence to accredit the drug for these results. The statements of Drs. Weidman and Arnold in regard to the relationship of granulomas to other infectious diseases were most interesting. The first patient did have tuberculosis; in fact, the organism was demonstrated in the tissue of the liver and by guinea pig inoculation. Other areas of the liver disclosed Histoplasma capsulatum. It is also striking that of 88 cases of histoplasmosis reported 4 have been associated with some form of lymphoblastoma. Reports have shown the association of tuberculosis and histoplasmosis to be unusually common.

NEUTRALIZATION TESTS FOR DIAGNOSIS OF HUMAN VIRUS ENCEPHALITIDES

PETER K. OLITSKY, M.D.
and
J. CASALS, M.D.
New York

The virus neutralization test is important because it can be used to help determine the prevalence of a disease, the geographic dissemination of its virus, the titer of antibody in an antiserum or the principles underlying the immunologic factors of an infection. One can with known virus demonstrate its specific antibody, and one can with known antibody reveal the identity of a virus. The test is simple in application when an appreciable amount of antibody is present; the antibody is detected by adding undiluted fluid, such as blood serum, which contains suspected antibody to suspensions which contain a known amount of virus. After varying periods of contact at certain temperatures, the mixture is injected by definite routes into selected species of animals, which are then watched for virus effect (i. e., no neutralization) or for no effect whatever (i. e., neutralization). However, when the serum contains antibody sufficient to neutralize only 1, 5, 10 or even 25 units of virus instead of hundreds of thousands of units, then it is like the task of Sisyphus—without end and, for the moment, without hope—to explain or indicate the significance. This is not intended, however, as a disquisition on the significance of serums containing borderline or traces of neutralizing substance. This is a report on the methods of performing the test which laboratories have evolved from experience; it will give a fairly accurate picture of a practical test and some of the underlying principles.

THE VIRUS ENCEPHALITIDES

The subject is limited to the human virus encephalitides. They are as now identified: (*a*) primary virus infections; (*b*) suspected, primary virus infections, and (*c*) virus encephalitides caused by familiar viruses not

---

From the Laboratories of the Rockefeller Institute for Medical Research.

ordinarily encephalitogenic. Poliomyelitis requires special consideration and will not be discussed here.

The primary virus encephalitides comprise Eastern equine encephalomyelitis, Western equine encephalomyelitis, Venezuelan equine encephalomyelitis, St. Louis type encephalitis, Japanese B encephalitis, Russian Far East (tick-borne, spring-summer) encephalitis, acute hemorrhagic meningoencephalomyelitis (leukoencephalitis), lymphocytic choriomeningitis, pseudolymphocytic choriomeningitis, swineherd's disease, louping-ill, acute encephalitis due to rabies and Sabin B virus. The first six are known as the summer, or epidemic, encephalitides (of which Eastern and Western equine and St. Louis encephalitis are prevalent in this country); the remainder, as endemic virus encephalitides. They have been called the arthropod-borne virus encephalitides by Hammon and Reeves.

The suspected primary virus encephalitides are newly discovered, and their role is significant because antibodies have been found in the blood of man and the viruses are neurotropic in laboratory animals. Clearcut clinical infections of the encephalitic type are yet to be seen. The viruses are as follows: West Nile, Bwamba fever, Semliki forest, Bunyamwera and Hammon-Reeves, California. The first two have been recovered from the blood of man, the remainder from mosquitoes only. Other suspected primary virus encephalitides are von Economo's disease and acute disseminated encephalomyelitis, the virus etiology of the two is not as yet established.

Virus encephalitides can be caused by ordinarily nonencephalitogenic viruses, which are those of herpes simplex, measles, lymphogranuloma venereum, mumps and infectious mononucleosis (probably due to a virus).

While human secondary or postinfection encephalitis has not been shown as yet to be caused directly by a virus, the malady does follow within the definite time of a few days to a few weeks various virus infections, such as measles, mumps, influenza, chickenpox, vaccinia, smallpox, infectious hepatitis and after vaccination against smallpox and rabies. The group is here mentioned because its differentiation from the virus encephalitides is sometimes required.

Although this list of encephalitic infections is lengthy, certain of the known general principles, the practical application and the methods of procedure of the neutralization test may be applied to almost all the mentioned maladies and their viruses; later on some noteworthy exceptions to general rules will be brought out.

CERTAIN GENERAL PRINCIPLES

The Time Factor.—At the outset it is admitted that the nature of the neutralization reaction is unknown. It is generally accepted, however, that the presence of significant amounts of neutralizing antibody indicates previous exposure to and infection by a virus, even though in many instances in the absence of apparent disease. This factor is the basis of the "two or three phase" test; i. e., under ideal conditions a specimen of serum obtained as early as possible during the acute phase of illness, another one or two weeks after the onset and a third, if necessary, taken still later, three to eight weeks after the onset, are subjected to the neutralization test. Since infection by a virus may be clinically inapparent, normal persons may show specific neutralizing antibody; hence a single positive specimen may be misleading, especially if the person has lived in areas in which the virus is endemic, as are St. Louis and Western equine virus in California and Washington (Buss and Howitt[1]; Hammon[2]). The reason for selecting the intervals from the earliest time to eight weeks after onset for test is that this antibody appears at varying times after infection with different viruses. In Western equine virus infection neutralizing antibody is evident as early as the fourth day after onset; in St. Louis and Japanese B encephalitis, three to seven days to three weeks; in lymphocytic choriomeningitis, not until about the sixth to eighth week after onset.

Comparative Tests.—It becomes apparent that the success of a diagnostic procedure of virus neutralization depends on the precision with which, in the comparison of serums obtained in the acute and convalescent stages of infection from the same patient, a definite increment of antibody in the later sample is revealed. To measure this increase in antibody (or in the protective power of an antiserum) one of two methods may be used. (1) Undiluted serum is tested against varying quantities of virus; for example, acute-phase serum may show no neutralization of as little as 10 units of virus, serum of one week after onset, may neutralize 100 units and that two weeks after onset 100,000 units of virus, the limit of this hypothetic test. At the limit, however, no difference between two different serums can be discerned, unless (2) the method of Morgan and Olitsky[3] is employed. They offered evidence to show that the capacity of undiluted serum to neutralize virus may not be different for different samples except by means of graded serum dilutions, in which a true antibody titration is made; then the finer shades or even pronounced degrees of difference between serums are manifested.

Animals Used and Route of Injection of Serum-Virus Mixtures.—There are two choices of laboratory recipients for serum-virus mixtures, when the neutralizing capacity of a serum is to be tested: first, the serum-virus mixtures are injected into an animal which is uniformly and highly susceptible. For the encephalitis viruses this is generally the albino mouse; however, for the Sabin B virus rabbits are used, and often for lymphocytic choriomeningitis the guinea pig is used. A second choice way is the injection of serum-virus mixtures into developing chick embryos (Burnet, Keogh and Lush[4]). As a rule the latter technic merely supplements the one employing animals or is used only for special purposes.

When the mouse is the animal of choice one takes into account its strain and age. A selectively inbred strain proved to be of high and uniform susceptibility, such as the Swiss W or the Rockefeller Institute strain, should be used; Casals and Schneider[5] have demonstrated that such animals may be essential for certain viruses. The age of the mouse is also important. It has been shown[6] that an increasing resistance develops in

PROCEDURES OF THE NEUTRALIZATION TEST

The neutralization test now to be described is that performed in our laboratory for more than twenty years; it includes the modification which Drs. H. R. Cox, C. G. Harford, I. M. Morgan, A. B. Sabin and other associates have introduced from time to time.

Preparations of Dilutions of Virus and Serum.—The stored, frozen suspension when thawed offers a 1:5 dilution of virus, which with an equal amount of serum becomes a 10^{-1} dilution. From the thawed suspension, dilutions as needed of 1:50, 1:500 and so on are made for final virus dilutions of 10^{-2}, 10^{-3} and so forth. The diluent is 10 per cent rabbit serum in isotonic solution of sodium chloride. The tubes receiving virus are kept in a vessel containing ice in order to keep the material cold until the time for injection in the animal. Of each dilution to be tested, 0.2 cc. is placed in the tube for testing. To each is added 0.2 cc. of undiluted, negative human serum. (If this is not available 10 per cent *normal rabbit serum can be substituted.) This is the* control series; for the test series the unknown serum for diagnosis is added instead. The tubes are incubated at 37 C. (water bath) for two hours; then they are placed in ice water until the contents is injected intracerebrally in animals (5 mice at least for each dilution).

The dilutions of virus to be used as control are such that at the higher dilutions all animals will survive and at the lower all will succumb. For the test serum, dilutions should be employed which indicate either no neutralization or neutralizations of at least 1,000 LD_{50} units of virus. For example, if the LD_{50} of the virus employed is generally 10^{-8}, the control series should be made up with virus dilutions of 10^{-6}, 10^{-7}, 10^{-8} and 10^{-9} and the test serum series with dilutions of 10^{-4}, 10^{-5}, 10^{-6} and 10^{-7}. When two or three phase serums are studied in a comparative way, Hammon [17a] has advised the use of fivefold dilutions of virus instead of tenfold, as is done here and elsewhere.

Highest dilutions of the test series should be injected into animals first, and the control series should be introduced last. Mice are observed for ten days for the equine viruses, except for recent isolations, which may be delayed in effect; then fourteen days should suffice, as for St. Louis encephalitis virus. For Russian Far East and Japanese B encephalitis virus three weeks of observation are required. Animals that die within twenty-four hours in equine virus tests are presumed to have succumbed from nonspecific causes. In the case of other encephalitis viruses deaths occurring up to forty-eight hours should be considered nonspecific; deaths on the third and later days should be ascertained as being caused or not caused by the virus inoculated intracerebrally. Care must be taken to eliminate the characteristic Theiler's virus disease arising spontaneously in mice (flaccid paralysis; muscular atrophy; apparent well-being otherwise of the affected animal) after inoculation of the serum-virus mixtures of the neutralization test. Finally, in such cases as the Russian Far East encephalitis virus, in which the incubation period is prolonged over several days and the animals are highly susceptible to extraneural exposure to the virus, care should be taken to isolate the inoculated animals by dilutions, i. e., all mice receiving the same dilution should be placed in one box, and sick and dead mice should be promptly removed from the group. This precaution is to avoid secondary, contact infections not related to the material injected.[14]

If it is essential to obtain information concerning the significance of neutralization with low multiples of LD_{50} virus,[14] tests can be repeated by the more sensitive extraneural (peripheral) method of Olitsky and Harford [7] or its modification by Lennette and Koprowski,[8] as already mentioned; these tests, of course, require special facilities, as has been stated. Furthermore, by this method there may at times be a tenfold diminution in the titer of virus; the whole range of virus dilutions should therefore be included. The success of the test will depend on the use of larger numbers of mice: at least 10 for each dilution.

In comparative tests with acute and convalescent serums from the same person, in cases in which additional information is desired on the more exact antibody content, the method [3] of serum dilution may be pursued to advantage. When dilutions of the serum are carried out, the test may then be performed either with constant amounts of virus, e. g., 10 or 100 LD_{50} units, or with varying amounts of virus diluted fivefold or tenfold.

SUMMARY

A description is here given of the neutralization test for the diagnosis of human virus encephalitides, including remarks on certain of its general principles and the details of the technic employed in this laboratory.

ROENTGENOGRAMS OF THORAX THAT SUGGEST CARCINOMA OF STOMACH

B. R. KIRKLIN, M.D.
and
EVA L. GILBERTSON, M.D.
Fellow in Roentgenology, Mayo Foundation
Rochester, Minn.

Diagnosis of early malignant lesions at the cardia of the stomach has long been considered difficult from both clinical and radiologic points of view. The cardia has been referred to as the silent region of the stomach because there are seldom any characteristic early symptoms of pathologic conditions of the cardia. During roentgenoscopic examination a lesion in this region can be overlooked unless the roentgenologist is thinking of it and proceeds with appropriate and thorough methods of search.

Until the recent years when improvements have been made in methods of anesthesia and particularly in the technical approach by transthoracic resection of the stomach, there has been little incentive for improvement of the means of diagnosis of carcinoma at the cardia because so little could be done therapeutically for patients with this disease.

Transthoracic resection of the stomach now has become a generally accepted surgical procedure, and a number of patients can be benefited materially if diagnosis is made early enough, before metastasis has occurred. For this reason any adjunct to early diagnosis is worthy of consideration.

ROENTGENOSCOPIC OBSERVATIONS

Roentgenoscopic diagnosis of carcinoma of the cardia has been described in the literature (Stewart and Illick,[1] Buckstein [2] and Kirklin [3]). In the majority of

Read befor[illegible] at the Ninety-Fifth Annual Session of the [illegible], San Francisco, July 3, 1946.

(Footnotes on next page)

cases the diagnosis may be made most readily by examination while the patient is in the vertical position. Then, in some cases, the diagnosis can be confirmed by examination of the patient while he is in the recumbent position. Small polypoid carcinomas at the cardia often will be missed if examination is made with the patient only in the recumbent or Trendelenburg position because small lesions may be obscured by the barium.

In many cases of carcinoma of the cardia the lesion can be recognized, or at least strongly suspected, at the beginning of roentgenoscopic examination of the stomach when the patient stands behind the screen and before the opaque meal is given. Normally the gas bubble at the cardia is smoothly symmetric and transradiant. A tumefactive mass which projects from the medial wall into the gas bubble can be seen at this time. More extensive tumefactive or infiltrative lesions may cause a deformity of the fundus of the stomach or even complete absence of the gas bubble.

Barium should be given slowly and each swallow watched as it passes through the lower part of the esophagus into the stomach. Signs of a lesion at the cardia for which the roentgenologist should look are: (1) distortion or partial stenosis of the lower part of the esophagus with or without dilatation above this area, (2) abnormally retarded outflow of barium into the stomach (due to partial obstruction by the growth), (3) continuous outflow of barium instead of normal spurting (indicating involvement of the esophagogastric junction with loss of normal sphincter-like control) and (4) polypoid growths which project as rounded prominences and cause deviation of the path of the barium. Less frequently the column of barium splits as it hits the tumor.

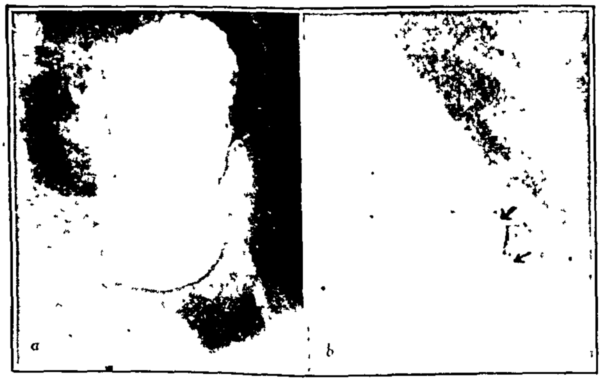

Fig. 1 (*a*).—Moderately extensive carcinoma at the cardia; (*b*), the thorax in the same case, immediately after roentgenoscopic examination of the stomach. The barium-coated, lobulated, malignant mass may be seen on the medial portion of the gas bubble of the cardia.

After a small amount of barium has been given, pressure should be applied over the dependent portion of the stomach in order to force the barium up into the cardiac portion. In this way the mucosa is coated and further study of the internal relief pattern is possible.

Other shadows which are seen occasionally in the gas bubble and which must be differentiated are: 1. Apex of the heart (pulsates and disappears from bubble on deep inspiration): In a routine roentgenogram of the thorax the shadow of the heart seldom causes any diagnostic difficulty, because the roentgenogram is taken after the patient has inspired deeply. 2. Spleen (on greater curvature side): Malignant lesions of the cardia are most often on the side of the lesser curvature. 3. Glandular metastatic growths or other masses (uncommonly seen): All these shadows are smooth, sharp and regular in margin, and in the roentgenoscopic examination with barium the overlying rugae are seen to be normal.

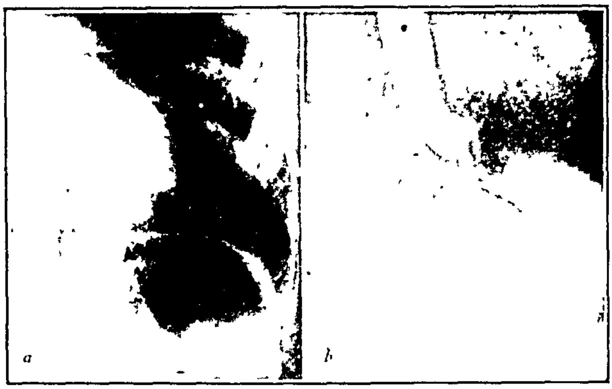

Fig. 2 (*a*).—Thorax with gas bubble of the cardia in which a lobulated mass can be seen on the medial aspect of the gas bubble; (*b*) esophagus and stomach in the same case, showing annular carcinoma of the lower part of the esophagus and the cardiac portion of the stomach.

Benign tumors in the cardia are infrequent. Therefore, when a tumor is present it is likely to be malignant. Other lesions which must be differentiated from carcinoma at the cardia are benign stricture and diverticulum of the lower part of the esophagus and cardiospasm. Extension of carcinoma of the esophagus into the cardiac end of the stomach produces a deformity similar to that produced by carcinoma which originates in the cardia and extends into the esophagus.

ROENTGENOGRAPHIC OBSERVATIONS

An ordinary roentgenogram of the thorax of the average-sized person generally includes the upper portion of the abdomen along with the thorax. This, then, includes the cardiac end of the stomach, and the gas bubble of the stomach is visible in the majority of cases. Therefore, if a mass is present it is visible within the gas bubble (fig. 1).

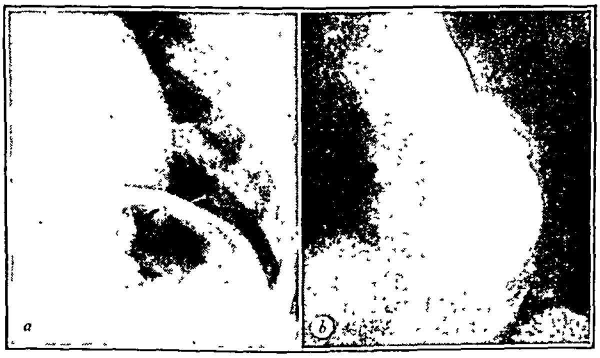

Fig. 3 (*a*).—Thorax: there is an irregular mass projecting from the medial wall of the cardia. The diagnosis of carcinoma was confirmed at operation; (*b*) same case showing the esophagus and stomach three weeks after a successful transthoracic, transdiaphragmatic resection of the lower part of the esophagus and the cardiac portion of the stomach.

3. Kirklin, B. R.: Roentgenologic Diagnosis of Cancer of the Cardia, Am. J. Roentgenol. **41:** 873-878 (June) 1939.

During 1945, 68 cases of tumor of the cardiac portion of the stomach with or without involvement of the esophagus were encountered at the Mayo Clinic. The lesion in each case was seen on roentgenoscopic examination. In some of these cases the diagnosis was suspected from the roentgenogram of the thorax; hence, this roentgenogram was reviewed in each case. When this was done a tissue mass which appeared to be soft and which projected from the lesser curvature side of the stomach into the gas bubble was observed in 35, or about half, of the cases. Although the diagnosis may not be made definitely when this projection is observed, existence of a lesion should be suspected and permission to carry out further roentgenoscopic examinations of the stomach should be requested.

In 21, 31 per cent or about a third, of the cases the mass caused an obvious defect. In several cases the deformity was as obvious in the roentgenogram of the thorax as in the roentgenogram of the stomach which was taken with the patient in a recumbent position (figs. 2 and 3). In some cases it was more obvious. In another 14 cases the defect was less obvious but was sufficiently apparent for the examiner to suspect the presence of a tumor and to request further study of the stomach. Lesions were seen more easily in roentgenograms in which the exposure was relatively heavy than in those in which it was light.

SUMMARY

The roentgenologic diagnosis of carcinoma of the cardiac end of the stomach is described. The importance of observing the air-filled upper segment is stressed because many diagnoses can be made or suspected without, or before, the use of radiopaque mediums. This segment can be observed on roentgenoscopic examination and also in routine roentgenograms of the thorax. A shadow which is caused by a tumor mass in the cardia and is seen in the gas bubble will sometimes be so clearly visible that the diagnosis can be made or at least suspected from this examination alone.

ABSTRACT OF DISCUSSION

Dr. Wilbur Bailey, Los Angeles: Dr. Kirklin's method of diagnosing cancer of the fundus of the stomach without even using barium is somewhat demoralizing to those of us who not only examine patients in the upright position with barium but then rotate them into numerous different positions when they are supine. Even then the diagnosis of carcinoma is difficult to make. Dr. Kirklin is to be congratulated on discovering so many carcinomas in films which were made for the purpose of examining the chest. On a few occasions my associates and I have made similar discoveries and have felt that we had accomplished something decidedly out of the ordinary. It is always well carefully to examine the left leaf of the diaphragm above the stomach bubble. The interval between the base of the lung and the stomach bubble should be no greater than the thickness of the left leaf of the diaphragm and the stomach wall. When this thickness exceeds more than a few millimeters, one should suspect infiltration of the stomach wall. Suggestions have been made that by way of economy 11 by 14 or 14 by 14 inch (28 by 36 or 36 by 36 cm.) size films should be used in thoracic examinations. Under these circumstances the left upper quadrant of the abdomen and the stomach bubble might be eliminated entirely—a fact which would make such film economy seem undesirable. Dr. Kirklin has done a beautiful piece of work, and I am sure we will all keep our eye on the left upper quadrant in roentgenograms of the chest from now on.

PROPHYLAXIS AGAINST OPHTHALMIA NEONATORUM

Clinical Comparison of Penicillin and Silver Nitrate: A Preliminary Report

H. CHARLES FRANKLIN, M.D.
Memphis, Tenn.

Sixty-seven years ago Credé, an obstetrician of Leipzig, Germany, first used silver nitrate in prophylaxis against ophthalmia neonatorum. With a small glass rod he instilled a single drop of 2 per cent silver nitrate into each eye of the newborn immediately after birth. Before the instillation, the eyes were cleansed with ordinary water and, afterward, were "cooled for twenty-four hours by means of a linen flap which had been saturated with salicylated water (2:100)."[1]

The silver nitrate drop method for prophylaxis became popular almost immediately and has remained so up to the present time. In Johnson's digest of the laws relating to ophthalmia neonatorum (1940), silver nitrate is mentioned most frequently as a preferred germicide.[2]

However, an element of opposition has existed. Even during Dr. Credé's time, objection arose because of the intense irritation which silver nitrate occasionally produced.[3] Hartman has placed the incidence of chemical conjunctivitis at about 4.3 per cent.[4] Von Hahn pointed out that silver nitrate will become more concentrated through the evaporation of the water unless the bottle is tightly stoppered. Drops left at the mouth of a bottle may form crystals; when the bottle is used for the next patient these crystals may be washed into the eye.[5] According to Stein, when a solution of silver nitrate decomposes with time there is a liberation of minute quantities of nitric acid, which causes severe irritation.[3] Bunney pointed out that if the solution is kept in an ampule containing yellow wax, the yellow wax will cause the silver nitrate to deteriorate to give an acid solution with a p_H of about 2.2 with a deposition of a black precipitate on the walls of the ampule.[6]

The solubility of silver nitrate is 75 per cent at a temperature of 86.1 F.[4] Thus there exists the danger of using a solution of a concentration higher than intended. Instances are recorded of infants being made blind by the use of a solution too high in concentration.[5]

The instillation of a 1 per cent solution of silver nitrate into the adult eye causes pain. I had a drop of fresh 1 per cent silver nitrate instilled into the conjunctival sac of one eye. An immediate painful discomfort was experienced, associated with lacrimation, conjunctival redness and the formation of a white curdlike exudate. I experienced some residual discomfort for four hours after this instillation.

Pharmacologically, silver nitrate is designated as a caustic, an astringent and a disinfectant. The dis-

infectant action of the compound is due to the free silver ion; its bactericidal property is a result of its combination with the protein of the micro-organism. Unfortunately, it also combines with proteins of the tissues; this explains its painful and destructive action.[7]

The most serious criticism of the use of silver nitrate is the doubtfulness of its value in the prevention of infectious acute conjunctivitis of the newborn. In 1935 Lehrfeld analyzed the records in 28,000 births occurring in six hospitals over a period of five years. He found the incidence of ophthalmia neonatorum to be 2.2 per cent.[8]

During the latter part of the nineteenth century, inflammation in the eyes of the newborn was thought to be of gonorrheal origin. Even as late as 1915 some still held to this opinion, for Van Blarcom wrote to stress that other causes were possible.[9] Thomas in 1928 called attention to the fact that Staphylococcus aureus can be the causative organism of acute purulent conjunctivitis of the newborn.[10] Among recent investigators extensive work has been done by Sorsby and associates in England in determining the causative organisms. In a series of 591 cases of ophthalmia neonatorum, published in 1942 and 1944,[11] the staphylococcus was most frequently the causative organism. The gonococcus was next in frequency, bacilli (diphtheroids predominant) third, and other cocci (gram-positive cocci, meningococci and pneumococci) fourth.

Today the term ophthalmia neonatorum is no longer synonymous with gonorrheal ophthalmia. It is now applied to all inflammations of the eye occurring within two weeks after birth. The time element of "within two weeks" is that usually found in the laws governing prophylaxis.[2]

Now, as before, the gonococcus is the organism which demands most attention for the prevention of blindness. But according to Thompson conjunctivitis caused by the pneumococcus, if once well established, can be equally destructive.[12] Ideal prophylaxis would be that which would destroy or inhibit the growth of these two organisms and as many other causative organisms as possible.

Since the discovery of penicillin, investigators have turned their attention toward its properties in relation to the eye. In 1929 Fleming used the human conjunctiva to test his newly discovered crude filtrate of penicillin for irritation. Irrigation every hour for a day produced no irritating effect.[13] Leopold and La Motte demonstrated that penicillin does not pass through the cornea into the aqueous humor of the rabbit's eye unless the cornea has been abraded or has become inflamed. They applied 4 drops of penicillin in isotonic solution of sodium chloride in a concentration of 500 Oxford units per cubic centimeter into the conjunctival sac. They also showed that corneal epithelium regenerates at approximately the same speed with hourly local applications of penicillin as when uninfluenced regeneration is allowed to take place.[14]

On the other hand, Struble and Bellows sh when a concentration of 20,000 units of penici cubic centimeter of isotonic solution of sodium ch and an excess of solution is used penicillin does pe trate the cornea. They also stated that constant contact of penicillin in a concentration of 20,000 units per cubic centimeter of isotonic solution of sodium chloride with the cornea of a rabbit will produce no visible change after staining with fluorescein. A solution containing 10,000 units per cubic centimeter dropped into the conjunctival sac of the human eye will produce only slight smarting but no alteration in the corneal epithelium as revealed by examination with a slit lamp and fluorescein staining.[15]

Von Sallmann, also using rabbits' eyes, found that the intravitreal injection of 10 to 100 Oxford units of penicillin does not cause any damage to the retina, lens or optic nerve. Only negligible lesions were produced by the injection of 250 and 500 units.[16] According to Tooke, penicillin can be safely injected into the aqueous humor of the adult eye in concentrations of 4,000 to 6,000 units per cubic centimeter.[17] Ingalls flushed the anterior chamber of the eye with 20 cc. of a solution of penicillin (containing 3,300 units per cubic centimeter) after surgical treatment of penetrating wounds of the cornea, and satisfactory results were obtained.[18]

Patients with gonorrheal ophthalmia have been successfully treated with penicillin. Griffey reported the treatment of a patient with gonorrheal conjunctivitis by the use of penicillin given intramuscularly.[19] McCullough reported a case of sulfathiazole-resistant gonococcic conjunctivitis in an adult which yielded to a combination of topical (1,000 units per cubic centimeter) and parenteral administrations of penicillin.[20] Seelig treated a patient by subconjunctival injections and local instillations (500 units per cubic centimeter).[21] Lewis reported the use of penicillin, local (1,000 and 2,500 units per cubic centimeter) and systemic administrations combined, in the treatment of 30 patients with results better than those obtained with the use of sulfonamide compounds.[22]

Bland and Wilson in Egypt were disappointed by the use of drops of calcium penicillin (500 Oxford units per cubic centimeter) locally in the treatment of 11 patients with gonorrheal ophthalmia. Eight of these were cured in an average of six days, but sulfonamide drugs were resorted to in 3 patients.[23]

Vorisek and Evans reported a drug-sensitization reaction following a second course of penicillin drops (500 and 250 units per cubic centimeter) in the local treatment of a patient with severe gonorrheal ophthalmia. The reaction was characterized by ptosis of the upper eyelid, by thick, red, leathery eyelids and by a slight fissuring of the epithelium of the cutaneous surface.[24]

Sorsby and Hoffa in 1945 reported the treatment of ophthalmia neonatorum in 47 infants with only the local application of penicillin in the form of drops. Concentrations of 500, 1,000, 1,500 and 2,500 Oxford units per cubic centimeter were used, and the results became more satisfactory as the concentration of penicillin in the drops increased. Twenty-two infants were treated with a concentration of 2,500 Oxford units; there were 21 cures. The causative organism of the therapeutic failure was a diphtheroid. Included in this group of 22 infants were 5 with gonorrheal ophthalmia. Thirteen of the 22 were cured clinically within forty-eight hours, and the remaining 8 within one hundred hours. These authors stated that the drug is well tolerated by the infants' eyes; occasionally a mild transitory flushing of the conjunctivas may be observed.[25]

Sorsby later supplemented the previously reported cases with an additional 38 cases. The results in this series were equally satisfactory except for 2 failures. The causative organisms of these failures were the gonococcus in one and a diphtheroid in the other. The same concentration of penicillin was used as before, but more frequent instillations were made.[26]

These reports indicate that penicillin in therapeutic concentrations is noninjurious to the vital structures of the human eye. They show that penicillin is an effective therapeutic agent in the treatment of gonorrheal ophthalmia. The significant work of Sorsby and Hoffa demonstrates that penicillin in adequate concentration appears to be effective in the treatment of ophthalmia neonatorum when applied locally.

PROPHYLACTIC INSTILLATION OF PENICILLIN

The foregoing facts suggest that penicillin may be an effective prophylactic agent against ophthalmia neonatorum when used in drops and in several respects may be superior to silver nitrate. Penicillin in proper concentration is nonirritating, nonpainful, nondestructive and effective in the treatment of ophthalmia neonatorum.

On the other hand, silver nitrate is temporarily destructive to the conjunctiva, as was first demonstrated by Credé and Hörder.[3] This destruction is observed clinically as a chemical conjunctivitis. That it is painful has been stressed. Silver nitrate deteriorates with time and with exposure to improper containers. But the most important consideration is the danger of permanent injury to the eyes as a result of the accidental use of a too concentrated solution of the silver nitrate.

The present study was undertaken to evaluate clinically the use of penicillin in the form of drops for prophylaxis against ophthalmia neonatorum and to compare it with silver nitrate as commonly used for this purpose.

METHOD

For a four month period (beginning July 1, 1946) penicillin was used for prophylaxis in the eyes of each newborn infant delivered at the John Gaston Hospital, Memphis, Tenn. For comparison silver nitrate was used for a three month period.

The infants were followed in the hospital for evidence of ocular abnormalities and, through the cooperation of the Memphis and Shelby County Health Department, were followed in the home for the first two weeks of life. The eyes of the infants were examined by public health nurses between the fourteenth and seventeenth days of life.

Aerobic, anaerobic and carbon dioxide cultures were run on specimens obtained from the conjunctivas of infants exhibiting pus in their eyes.[27]

SOLUTIONS

Penicillin was used in the form of the crystalline sodium salt of penicillin. A concentration of 2,500 units per cubic centimeter of diluent was used throughout. Sterile isotonic solution of sodium chloride was used as a diluent throughout, except for one and one-half months when sterile distilled water was used. A fresh solution was made as needed but was not kept longer than a week. It was kept refrigerated below 59 F. (15 C.) when not in use.

Silver nitrate was used as a 1 per cent solution in distilled water. A fresh solution was made each day and dispensed from the drug room in a new dropper bottle.

PROCEDURE

Prophylaxis of the eyes of each newborn infant was carried out in the delivery room within one hour of birth, before the infant went to the nursery. The eyelids and adjacent area of the newborn infant were cleansed of contaminating secretions by gently wiping with a large ball of cotton from the inner canthus outward. The eye was closed at the time. Gauze was then used on the fingers for traction to open the eyelids while each eye was flushed thoroughly with 2 or 3 cc. of sterile isotonic solution of sodium chloride (or sterile distilled water when it was the diluent for the penicillin). One drop of penicillin solution was then instilled into the conjunctival sac of each eye.

Instillations were also carried out in the nursery. A single drop of penicillin was instilled daily in each eye of each infant for the first three days of life. The first midnight following the day of birth was considered the beginning of the first day of life. Instillations were made throughout the nursery at approximately the same time each day. Gauze was used on the fingers for traction to open the eyelids of each eye while 1 drop of penicillin was instilled. The hands were washed with soap and water before handling each infant.

PROPHYLACTIC INSTILLATION OF SILVER NITRATE

When silver nitrate was used ocular prophylaxis was carried out in the delivery room in the manner previously described, except that one drop of silver nitrate was instilled instead of penicillin and sterile distilled water was used for flushing the eyes. The infants did not receive any prophylaxis in the nursery.

RESULTS

A total of 1,710 infants (961 infants after the use of penicillin and 749 infants after the use of silver nitrate) were studied in the nursery. All neonatal deaths occurring among infants born in either period were excluded. Twenty (2.1 per cent) of 961 infants exhibited pus in one or both eyes during or after penicillin prophylaxis; 45 (6.0 per cent) of 749 exhibited pus after silver nitrate (table 1).

Approximately half of the 20 infants exhibiting pus after penicillin drops showed grouping of occurrence around the first and second days of life. The occurrence in the other half was sporadic (chart 1). The occurrence of pus in the eyes of 45 infants after the use of silver nitrate showed definite grouping on the day of birth and the first day of life.

[26] Sorsby, A.: Brit. M. J. 1: 903, 1945.

[27] A bacteriologic analysis will be treated separately in another article.

Abnormalities other than the presence of pus were noted in each group. Two hundred infants were followed from each group to evaluate the incidence of eyelid swelling, conjunctival redness and watery discharge. The degree of abnormality—slight, moderate or severe—was graded. Abnormalities occurred most frequently on the day of birth. Swelling of the eyelids was noted in 31 per cent of infants after penicillin prophylaxis and in 58 per cent after silver nitrate. Conjunctival redness was seen in 42 per cent after penicillin and in 72 per cent after silver nitrate. Watery discharge was least frequent and occurred in 2 per cent after penicillin and in 10 per cent after silver nitrate. Moderate and pronounced degrees only of these abnormalities are recorded in the foregoing analysis, while slight degrees are not. A slight degree of conjunctival redness or swelling of the eyelids can be produced by the infant's crying. Likewise a moderate degree can be converted to a severe one by crying; thus moderate and appreciable degrees are grouped together.

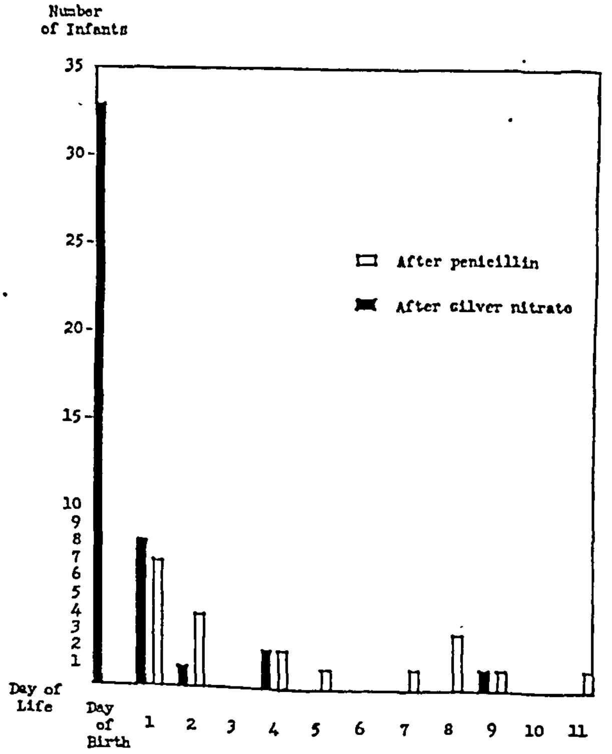

Chart 1.—Day of life when pus was first observed in infant's eyes while in nursery.

Table 1.—*Incidence of Infants Exhibiting Pus in Eyes While in Nursery After Each Method of Prophylaxis*

Method of Prophylaxis	Infants Exhibiting Pus	Total No. of Infants	%
Penicillin	20	961	2.1
Silver nitrate	45	749	6.0

A comparison between the incidence of swelling of the eyelids in relation to the day of life after each type of prophylaxis is made in chart 2. The occurrence of conjunctival redness is compared in chart 3.

The preceding comparison was made when sterile isotonic solution of sodium chloride was used as the diluent for dissolving the penicillin crystals and for irrigation of the eyes in the delivery room. During the time that distilled water was used for both purposes the eyes were not graded in the manner previously described, but no noticeable difference was observed clinically between its use and the use of saline solution. Since the latter causes less discomfort than does distilled water in the adult eye, it is probably to be preferred.

Gonococcic conjunctivitis did not develop in any infant in the group receiving penicillin prophylaxis, but in 1 premature infant in the silver nitrate group it did develop on the fourth day of life. The organism was identified by culture and confirmed by fermentation tests.

Table 2.—*Nurses' Reports from Study of Infants at Home During First Two Weeks of Life*

Condition of Eyes	Penicillin No.	Penicillin %	Silver Nitrate No.	Silver Nitrate %
Normal	672	93.7	479	96.0
Presence of pus	22	3.1	12	2.4
Other abnormalities (redness, swelling or watery discharge)	11	1.5	6	1.2
History of infection of the eyes related by mother	12	1.7	2	0.4
	717	100.0	499	100.0

FOLLOW-UP OBSERVATIONS

Nine hundred and sixty-one infants who received penicillin prophylaxis were discharged to their homes. The public health nurses made follow-up examinations on a total of 771 infants (80.2 per cent). Of these the follow-up of 54 infants could not be completed because they either were not residents of Shelby County or had remained in the hospital through the seventeenth day;

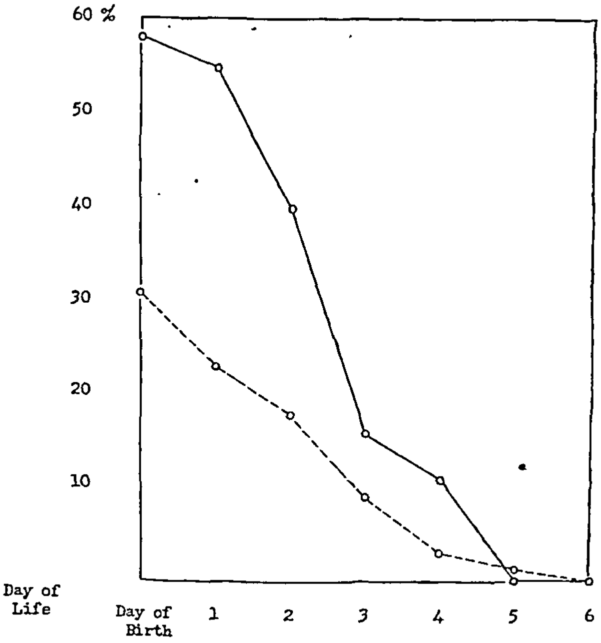

Chart 2.—Incidence of swelling of the eyelids after each method of prophylaxis: broken line, after penicillin; unbroken line, after silver nitrate.

or because of some other reason. Thus, a complete follow-up was made on a total of 717 infants (74.6 per cent).

Seven hundred and forty-nine infants who received silver nitrate prophylaxis were discharged to their homes, and a follow-up was made on a total of 558 infants (74.5 per cent). Of these the follow-up of 59 infants could not be completed for the reasons already mentioned, and thus a complete follow-up was made on a total of 499 infants (66.6 per cent).

After the use of penicillin for prophylaxis 672 infants (93.7 per cent) were normal at the time (fourteenth to seventeenth day) of the public health nurses' examinations (table 2). The mothers of this group stated that no abnormalities of the eyes had been seen after the infant had arrived at home. Pus was found in the eyes of 22 (3.1 per cent) at the time of the examinations. Other abnormalities—conjunctival redness, swelling of the eyelids or a watery discharge—were noted in 11 infants (1.5 per cent) by the visiting nurses. The mothers of 12 infants (1.7 per cent) stated that abnormalities of the eyes occurred prior to the time of examination. These abnormalities had cleared by the fourteenth to seventeenth days.

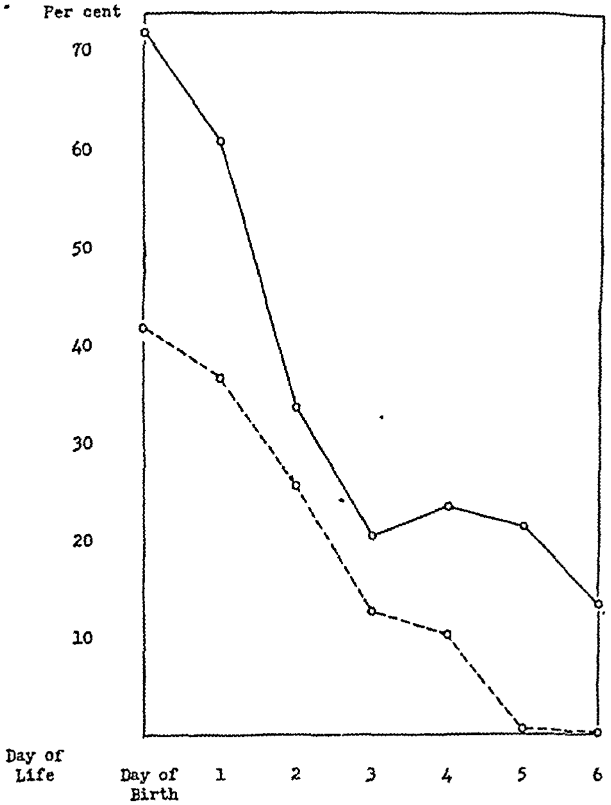

Chart 3.—Incidence of conjunctival redness after each method of prophylaxis: broken line, after penicillin; unbroken line, after silver nitrate.

After silver nitrate was used for prophylaxis 479 infants (96 per cent) were normal at the time of the examination in the home. Of those who exhibited abnormalities, pus was found in the eyes of 12 (2.4 per cent), and other abnormalities were noted in 6 (1.2 per cent). The mothers of 2 infants (0.4 per cent) stated that abnormalities of the eyes had occurred prior to the time of the examination but had cleared by the fourteenth to seventeenth days.

After penicillin prophylaxis, 4 of those who exhibited ocular abnormalities in the home were hospitalized. In 1 there developed an ocular infection on the fifth day of life (hospitalized five days), in 1 on the sixth day (hospitalized four days), in 1 on the eighth day (hospitalized three days) and in 1 on the fourteenth day (hospitalized seven days).

After silver nitrate prophylaxis 2 infants were admitted to the hospital. In 1 infant infection of the eyes developed on the tenth day of life (hospitalized sixteen days—concomitant infection of thrush of mouth), and in the other on the eleventh day (hospitalized four days).

The bacteriologic observations in all 6 infants were negative for the gonococcus.

COMMENT

Crystalline sodium salt of penicillin was used because of its stability. This form of penicillin does not require refrigeration while in the crystalline form. A solution of this form of penicillin retains its potency for at least one week if kept refrigerated below 59 F. (15 C.), provided that the p_H is over 5.5.[28]

In view of the fact that penicillin is not antiseptic but largely bacteriostatic, it was thought that multiple instillations probably would be necessary. Thus, it was decided arbitrarily to use four instillations, as has been mentioned.

That silver nitrate is irritating to the extent of pus formation is confirmed by the fact that a high percentage of infants in the group receiving silver nitrate prophylaxis exhibited pus on the day of birth and the first day of life. Likewise a high percentage of those infants exhibiting other abnormalities at this time was probably due to this irritation.

The cause of conjunctival redness, swelling of the eyelids and watery discharge in the group receiving penicillin was not determined in this study. Since the infant received penicillin prophylaxis through the third day of life, these abnormalities occurred prior to the completion of the prophylaxis. The abnormalities usually subsided before the prophylaxis was completed. Thus, it did not seem likely that possible hypersensitiveness to penicillin was the cause. None of the infants observed presented signs attributable to a drug-sensitization reaction such as those described by Vorisek and Evans.[24]

The actual cause of these ocular abnormalities is open to speculation. Any one of several factors, or a combination of them, might be responsible. Other than a nonsuppurative ocular infection, these factors might be trauma to the eyes by pressure during labor or delivery, irritation from the lubricant used during delivery or exposure to the atmosphere of an eye accustomed to being bathed in amniotic fluid.

It must be remembered that ocular prophylaxis after birth can be expected to protect an infant only from the contaminating secretions of the mother's birth canal. An infant's eyes may become infected by any one who handles the infant, both in the nursery and at home. In carrying out prophylaxis of the eyes cleanliness by washing the hands before handling each infant must be observed to avoid this source of infection and, more important, to avoid the spread of ocular infection from one infant to another. The use of gauze for traction of the eyelids serves a second purpose of preventing the fingers from coming directly in contact with the skin of the eyelids.

The incidence of infection of the eyes may be influenced by the coexistence of another type of infection in the nursery. During the period of penicillin trial there were two outbreaks of infectious diarrhea in the nursery. This was under control during the period of the silver nitrate trial.

---

[28] Personal communication from pharmaceutical firm.

A disadvantage of the method of penicillin prophylaxis as compared to that with silver nitrate is the probable need of four instillations instead of one. However, this disadvantage is outweighed by a number of advantages. The advantage of safety and of penicillin's painless instillation have been mentioned. All types of abnormalities of the eyes are less frequent during the first days of life when penicillin rather than silver nitrate is employed for prophylaxis. A solution of silver nitrate must be freshly made each day, but that of penicillin need not be made oftener than once a week. One need not fear that noxious substances will be produced by the deterioration of penicillin as they are by that of silver nitrate. If one suspects serious conjunctival contamination, it is convenient to be employing a prophylactic agent which can be used frequently and in any amount desired. The solution of penicillin may be used not only for prophylaxis but for treatment as well.

SUMMARY AND CONCLUSIONS

Penicillin and silver nitrate are compared in prophylaxis against ophthalmia neonatorum. A total of 1,710 infants were studied clinically in the nursery and in the home during the first two weeks of life. The incidence of the occurrence of pus in the eyes after each method of prophylaxis was determined. A comparison was made of the day of life on which the pus was first observed. The incidence of other abnormalities of the eyes was evaluated. The incidence of gonococcic conjunctivitis was determined. The number of infants hospitalized because of ocular infections that developed during the first two weeks of life was noted.

In the nursery, the occurrence of pus was approximately one third as frequent in the penicillin group as in the silver nitrate group. The occurrence of pus in relation to the day of life was sporadic in approximately half the infants in the penicillin group but showed grouping around the day of birth and first day of life in the silver nitrate group. Other abnormalities—conjunctival redness, swelling of the eyelids and watery discharge—were much less frequent in the penicillin group. In no infant in the penicillin group did gonococcic conjunctivitis develop, but 1 infant in the silver nitrate group did show gonococcic conjunctivitis on the fourth day of life.

While at home a higher percentage of those in the penicillin group exhibited pus and other abnormalities of the eye than of those in the silver nitrate group. Four from the penicillin group and 2 from the silver nitrate group were hospitalized. There were no cases of gonococcic conjunctivitis in either group during the first two weeks at home.

In the study of this series of infants penicillin compares favorably with silver nitrate as a prophylactic agent. Penicillin prophylaxis is to be preferred because danger of permanent injury to the eye is eliminated; an instillation is nonpainful; ocular abnormalities are less frequent during the first days of life; the solution of penicillin need not be made fresh each day; deterioration does not produce noxious substances; an excess of the solution may be used if desired, and the penicillin solution may be used for both prophylaxis and treatment.

Clinical Notes, Suggestions and New Instruments

THE USE OF NEOSTIGMINE METHYLSULFATE IN INFECTIOUS NEURONITIS

Report of a Case with Involvement of Respiratory Muscles

RUSSELL J. BLATTNER, M.D.
JAMES GOODFRIEND, M.D.
and
BAILEY D. WEBB, M.D.
St. Louis

The use of neostigmine has been advocated in the treatment of poliomyelitis[1] and other neuromuscular disturbances.[2] Whereas clinical results with this and similar drugs are equivocal in poliomyelitis,[3] encouraging results have been reported in the treatment of a case of neuronitis.[4] The present report concerns a case of infectious neuronitis in which neostigmine effected subjective and objective improvement during a critical period of respiratory difficulty.

REPORT OF CASE

C. V., a white boy aged 10, was admitted to St. Louis Children's Hospital on June 8, 1946. He had been well until two weeks prior to admission when he suffered an illness characterized by fever, malaise, lesions in the mouth and a maculopapular rash which began on the face. The disease was diagnosed as measles by the family physician. Measles was prevalent in the community at the time. Apparently the boy's recovery from this acute illness was complete. However, nine days after its onset, i. e., five days prior to admission, he began to complain of headache and of weakness in the legs. After about forty-eight hours the headache subsided, but nausea and vomiting followed. At this time weakness in both legs was associated with pain in the hamstrings, and there was stiffness of the back and the neck. He was observed to walk with a staggering gait. On the night before admission to the hospital he experienced difficulty in initiating urination. The remainder of the history was noncontributory. The child had been immunized against smallpox, diphtheria and tetanus.

On admission, physical examination revealed a well developed and well nourished boy. Slight ptosis of the eyelids was noted; otherwise the cranial nerves were intact. There was slight stiffness of the neck, and pain was elicited on flexion, but no definite rigidity was demonstrated. All deep reflexes in the lower extremities were absent, as was the right upper abdominal reflex. Reflexes in the upper extremities were equal and active. No response was obtained through plantar stimulation. No impairment of sensation was detected on careful examination. The finger to nose test was well performed with the eyes open

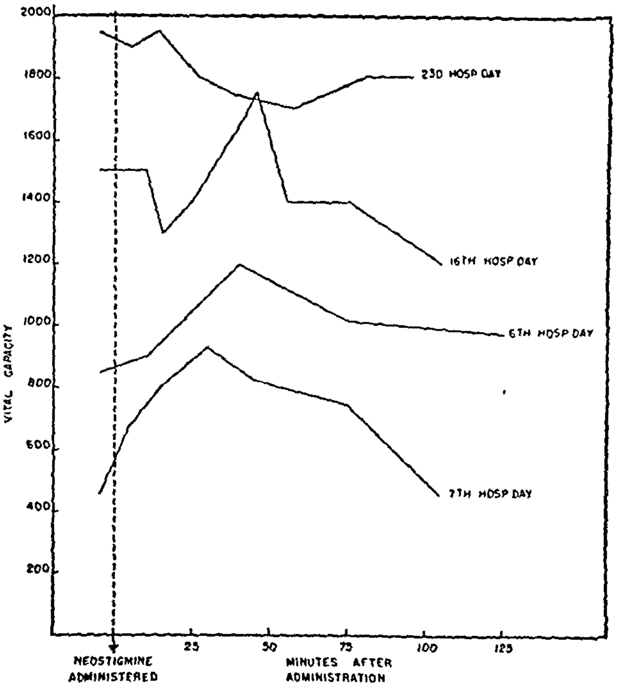
but only fairly well performed with the eyes closed. The heel to knee test was poorly performed bilaterally. Muscle tone was extremely poor in the hamstrings, the gastrocnemius and the soleus muscles of both extremities. On forced extension of the hamstrings, the patient complained of pain in the tendons. The muscles of the back were quite stiff, and the patient was not able to walk without support. Cerebrospinal fluid obtained on admission showed 1 cell per cubic millimeter, and the Pandy test was positive; the chloride content was 730 mg. and the protein level was 110 mg., per hundred cubic centimeters. Urinalysis revealed nothing abnormal. Study of the blood showed 14.5 Gm. hemoglobin, 10,000 white cells, with 67 segmented, 30 lymphocytes, 2 monocytes and 1 eosinophil, and adequate platelets. A diagnosis of infectious polyneuritis (neuronitis) was made.

The patient's condition was satisfactory until the fourth hospital day, at which time striking changes in the neurologic picture were observed. Cranial nerve examination now revealed the following: a slight blurring of vision but no decided impairment of extraocular movements; weakness and pain in masseter muscles; moderate facial weakness more pronounced on the right side; an increase in ptosis; palatal weakness and impairment in swallowing; partial paralysis of vocal cords; weakness of the sternocleidomastoids, and slow protrusion of the tongue with a fine tremor. Biceps jerks had become much less vigorous than on admission; the abdominal reflexes were difficult to elicit, and the reflexes in the lower extremities remained absent. The patient complained of paresthesia in the lower extremities and to some degree in the upper extremities. Vibratory sense (256) was absent in the lower but present in the upper extremities, and position sense was lost in the lower extremities. The flaccid paralysis which had been noted on admission was more pronounced. The patient was just able to raise his arms and legs from the bed. Weakness in the muscles of respiration was noted.



Effect of neostigmine methylsulfate on vital capacity. (The calculated normal vital capacity is 1,900 cc.)

Because of the rapid development of these adverse findings, a trial dose of neostigmine was deemed advisable, and 1 cc. of a 1:2,000 dilution of neostigmine methylsulfate was administered subcutaneously. Within forty minutes after the administration of the drug a definite change in the patient's condition was noted. He was able to raise both arms from the bed and to extend them. His speech and deglutition were strikingly improved. Although his legs were still weak, he could flex the knees and dorsiflex both feet. In view of this improvement, the administration of neostigmine was continued at regular three hour intervals. Within forty to forty-five minutes after each administration of drug, well defined improvement in voice and respiration was noted.

In order to obtain objective evidence and evaluate the apparent improvement in respiratory efficiency subsequent to the use of neostigmine, studies of the vital capacity were undertaken on the sixth hospital day. By means of a cylindrical spirometer, the vital capacity at rest was recorded as 850 cc. Immediately after this reading was made, 1 cc. of a 1:2,000 solution of neostigmine methylsulfate was administered subcutaneously, and at regular intervals thereafter determinations of the vital capacity were made. (See the accompanying chart.) A maximum increase was observed forty minutes after the administration of the drug, when the vital capacity was 1,200 cc. Within seventy-five minutes after giving the drug, it had fallen to 1,020 cc., and within 125 minutes it had returned to 975 cc. The patient was able to breathe more comfortably during the period of increased vital capacity, and the mild cyanosis tended to disappear. Also, as noted previously, muscular function was improved. Extension of the arms, which before the administration of the drug could be executed only after several jerking movements, was now accomplished smoothly. Appreciable relief from the painful spasm of the shoulder girdle and back lasted for a period of one-half hour to one hour.

Despite therapy, however, the patient became progressively worse during the next twenty-four hours. The effectiveness of neostigmine for relief of muscular spasm and for increase in vital capacity was reduced decidedly. Now the administration of neostigmine increased the vital capacity from a resting level of 450 cc. to a maximum of 930 cc. thirty minutes after the administration of the drug. The return to resting level occurred within an hour and forty-five minutes. At this time (seventh hospital day) studies made of the power of finger muscles likewise indicated maximum effect of the drug at thirty minutes. Thirty minutes after the drug was administered the work capacity of the right index finger against constant weight was doubled.

In the hope of obtaining some information as to the site of action of neostigmine, action currents from a flexor of the forearm in response to electrical shocks to the ulnar nerve were recorded before and after the usual dose of neostigmine on the eighth hospital day. With supramaximal shocks the amplitude of the potential was not increased by the drug. While this does not demonstrate that normal power of the muscle was present in either case, it does indicate that any improvement in power under this drug was not due to an effect on the nerve-muscle junction and was presumably, therefore, an action of the central nervous system. Records of the flexors and extensors of the wrist in voluntary movement seemed to indicate that the tendency of flexors to respond during extension, and of extensors during flexion, was decreased under neostigmine. Such a finding is, however, not conclusive since opposing muscles may be involved normally in controlling the movement of the wrist. In addition relaxation of emotional tension as the subject became accustomed to an unusual procedure may have contributed to the result.[5]

On the ninth hospital day the patient's respiratory distress was more pronounced, due in part to the aspiration of a small quantity of water. Resort to the Drinker respirator was necessary. In view of the information gained from the studies of vital capacity and the obvious relief of spasticity and muscular pain, the administration of neostigmine was continued at maximum dosage of 1 cc. of a 1:2,000 dilution given subcutaneously every two hours, even during the period when the patient was in the respirator. At this time the patient complained of some abdominal pain, but there was no increase in salivation. Atropine (1/150 grain, 0.4 mg.) was given once to counteract abdominal pain.

During the next four days, which were spent in the respirator, weakness of the muscles was extreme. However, at the end of this time the patient began to improve in all respects. On the thirteenth hospital day it was possible for him to remain out of the respirator all day. The administration of neostigmine was necessary only every three hours. Phonation had improved greatly; swallowing was accomplished with less difficulty; ptosis and facial paresis were less definite. All deep reflexes in both upper and lower extremities were still absent except for the left biceps jerk which was present inconstantly. Superficial reflexes were absent. The position sense in the lower extremities was impaired, and the patient complained of paresthesia in all extremities. The remainder of the sensory examination revealed normal conditions. After the thirteenth hospital day steady progress toward recovery was made. On the sixteenth hospital day further studies on vital capacity were attempted. The resting vital capacity at this time was recorded as 1,500 cc. A maximum rise to 1,750 cc. was observed fifty-five minutes after the administration of neostigmine. In view of this minimal response, the administration of the drug was discontinued on the seventeenth hospital day. At this time the electrical tests on the muscles which had been used on the previous occasion were repeated and the findings compared with those obtained for corresponding muscles of a normal child. In neither case was any effect of neostigmine noted—either on the response to electrical stimulation of the muscles or on voluntary motion to any significant degree.

---

[5] Electromyography was done by Dr. George H. Bishop in the Department of Neurophysiology, Washington University School of Medicine.

Effect of Neostigmine Methylsulfate on Normal Controls

	Vital Capacity (in Cc.)		Vital Capacity (in Cc.), Min. After Neostigmine						
Subject	Calculated	Actual	5	15	30	40	60	80	100
J. F.	2,400	2,800	2,800	2,750	2,700	2,700	2,720	2,750	2,650
A. B.	2,400	2,600	2,350	2,400	2,300	2,250	2,400	2,600	2,400
D. C.	2,100	1,800	1,850	1,750	1,800	1,800	1,800	1,720	1,750

Muscular strength and reflexes returned gradually. On the eighteenth hospital day spinal puncture revealed clear fluid that contained 1 lymphocyte per cubic millimeter and had a protein level of 415 mg. per hundred cubic centimeters. On the twenty-second day a trial dose of neostigmine methylsulfate was administered in an attempt to determine its effect on the tremor of the hands and on a mild spasm of the sacrospinalis muscle which were still present. No effect on either was noted. Repeated vital capicity readings on the twenty-third hospital day gave an average resting level of 1,950 cc. The vital capacity did not change within two hours after the administration of 1 cc. of a 1 : 2,000 dilution of neostigmine. Improvement continued, and the patient was discharged on the twenty-ninth hospital day. Follow-up examinations indicated gradual, steady return of muscle power, so that at thirty days after discharge all deep reflexes were present. No involvement of the cranial nerves was observed. Except for slight difficulty on running, the gait was normal. Two months after discharge no abnormalities whatsoever could be elicited.

COMMENT

The administration of neostigmine methylsulfate to a patient during the acute phase of infectious neuronitis resulted in remarkable subjective and objective improvement. Within thirty to forty-five minutes after the subcutaneous administration of the drug there was notable change in phonation and deglutition, relief from pain due to muscular spasm, greater ease of movement of the upper and lower extremities and an increase in vital capacity. In the acute phase of the disease, the response to neostigmine was progressively less both with respect to duration and to overall effect. In the latter part of the period of recovery, no effect due to neostigmine could be demonstrated.

The apparent improvement in the strength of the muscles might be interpreted as due to a decrease in spasticity of the antagonists rather than to an increase in the strength of the agonists. It is suggested that a reduction in hyperactivity had occurred at cord or higher levels due perhaps to an effect of neostigmine on the central nervous system. Kabat and Knapp [1c] who have made similar observations in subjects whose muscular spasm resulted from lesions of internuncial neurons have attributed this effect to an inhibition of proprioceptive reflex activity. A similar effect of cholinergic drugs on hemiplegias and other spastic conditions was described earlier by a number of French workers, quoted by Ward and Kennard,[2d] and has been investigated more recently by Kremer [2b] who demonstrated a depression of deep reflexes and a lessening of spasticity in patients with lesions of the pyramidal tract to whom neostigmine was administered intrathecally. Ward and Kennard [2d] have shown that monkeys to which cholinergic drugs were administered after unilateral ablation of areas 4 and 6 of the cerebral cortex recovered muscular function more rapidly and more completely than did control animals after the same operation. From a preliminary survey of a number of conditions which have muscular spasm in common, e. g., hemiplegia, cerebral infarctions and rheumatoid arthritis, Kabat [2a] concluded that the majority of patients improved remarkably after the administration of neostigmine. According to Kabat the improvement consisted not only in relief of spasm and pain but also in increase of the range of motion. Relief of the spasm in rheumatoid arthritis by means of this drug has been described by Trommer and Cohen.[2c]

Increase in vital capacity and relief of respiratory distress in this patient after the administration of neostigmine methylsulfate are less easily explained on the basis of lessened antagonist spasticity. However, spasticity of the muscles of the neck and back in general and of the accessory muscles of respiration in particular may have contributed to the respiratory difficulty. If so, relief of such spasm effected by neostigmine might account for the increase in vital capacity noted after the use of the drug. It is of interest that the effect of the drug disappeared as the vital capacity of the patient returned to the normal level for his calculated surface area. In similar experiments on normal patients of approximately the same age and size, no increase of vital capacity was observed after the administration of neostigmine (table 1).

CONCLUSION

Evidence is presented which indicates that neostigmine methylsulfate administered subcutaneously to a 10 year old boy suffering from infectious neuronitis was effective in increasing the vital capacity and in tiding the patient over a critical period of respiratory difficulty. It seems possible that in such cases increased vital capacity induced by the drug might obviate the necessity for the respirator. In this patient relief of pain subsequent to injection of the drug was noteworthy. Increase in muscular power and improvement in phonation and deglutition during the early stages of the disease were definite and reproducible. Later in the course of the disease these effects were less striking in character and more transitory. The suggestion is offered that the increased muscular and respiratory efficiency observed in this patient subsequent to the administration of neostigmine methylsulfate may have been brought about by relief of spasm of antagonistic muscles.

DISSEMINATED CHICKENPOX (PNEUMONIA AND NEPHRITIS)

CHARLES E. GRAYSON, M.D.
and
ELIZABETH J. BRADLEY, M.D.
San Francisco

The radiologist is usually confronted with several possibilities in the interpretation of roentgenograms of the chest in the presence of pathologic changes. The interpretation is increasingly dependent on associated clinical and laboratory data. The addition of cases with more detailed studies assists in the possibility of better differentiation of pathologic entities.

With the further recognition of various virus infections involving the lungs and their differentiation by serologic methods, there is greater assurance that the process is actually the result of the viral agent and not merely a concomitant or superimposed bacterial infection. The advent of more effective bactericides which are used, at times, as a therapeutic test against possible pathogenic bacteria enhances the assurance of virus etiology alone.

Among the virus diseases less frequently revealing pulmonary manifestations are those that affect the skin and mucous membranes primarily. Pneumonia, however, is not infrequently seen in measles and has been reported in smallpox contacts.[1] Disseminated chickenpox with pulmonary and renal lesions has been

recognized. Bullowa and Wishik[2] observed pneumonia in 0.8 per cent and nephritis in 0.1 per cent of 2,534 cases, with, however, pathogenic bacteria also present and thought to be the complicating agent. Gill[3] in a review of the literature showed nephritis as a complication in varying percentage, roughly 0.1 to 0.5 per cent with an interval of one to twenty-four days between the eruption and the onset of nephritis. Waring, Neubuerger, and Geever[4] reported some details of 8 cases in which the histologic appearance was considered as not being characteristic of the virus type of pneumonia. They reported 1 case complicated with pneumonia and a second fatal case with lobar pneumonia, encephalitis and nephrosis. Pathogenic bacteria were associated with the disease in both these cases, although Waring and his associates believed that the histologic observations in the fatal case were those of a virus type of infection. Rausch, Grable and Musser[5] reported a case of chickenpox in an adult with pneumonia. They considered that this was probably due to chickenpox, but there was apparent response of the fever to sulfathiazole therapy. The absence of leukocytosis was a factor in their consideration.

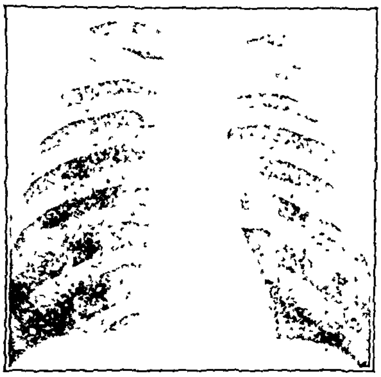

Fig. 1.—A few scattered, small, scarcely visible densities revealed by roentgenogram of chest on entry.

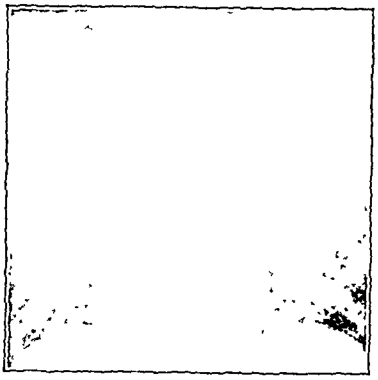

Fig. 2.—Pronounced increase in the pulmonary density in the perihilar and midlung areas; slight cardiac enlargement.

REPORT OF A CASE

The report of a case in which no evidence of bacterial infection was obtained is as follows:

History.—A white man aged 34, an American seaman, entered the isolation division of San Francisco Hospital for the first time on April 14, 1946. His complaints were fever of four days' duration with a rash for two days. The present illness began four days before entry when the patient noticed general malaise and fever followed by a few chills. After two days he lost his appetite, and a rash began to develop over his chest, arms, face and neck. A nonproductive cough developed one day later. His family history was noncontributory. He denied any association with tuberculosis. His past illnesses included measles, whooping cough and typhoid fever with pneumonia in 1923.

Physical Examination.—On entry examination revealed a well developed man who was not in acute distress. The temperature was 103 F., the pulse rate 85 and the respiratory rate 24. The skin showed a pleomorphic maculopapular and vesicopapular rash on the trunk, face and neck, and there were a few lesions on the arms and thighs. The lesions varied from macules 1 to 5 mm. in diameter to papules and vesicles of 2 to 5 mm. in diameter. Some older lesions were crusted and healing. They were surrounded by a red areola. The eyes showed a mild degree of conjunctivitis and there was an acute type of rhinitis with some dicharge. No Koplik's spots were visible, but there were some pleomorphic lesions in the mouth, as described previously. The lungs were clear to auscultation and percussion, although the patient coughed constantly throughout the examination. The abdomen and genitalia were not remarkable. The reflexes were physiologic.

A roentgenogram of the chest on entry revealed a few scattered, small, scarcely visible densities (fig. 1).

Laboratory Findings.—The Wassermann test of the blood was negative. On April 15, 1946 the icteric index was 12.6, the Takata-Ara reaction was negative. The level of total serum proteins was 5.0 Gm., with albumin 3.4 Gm. and globulin 1.6 Gm., per hundred cubic centimeters.

Four cultures of blood taken over a period of one month showed no growth of organisms.

Examinations of sputums were negative, except for normal flora in the respiratory tract. Pneumococci or hemolytic streptococci were not found.

Test for cold agglutinins on April 18, April 25 and May 2, 1946 were negative in all dilutions.

The determination of serum proteins on May 23, 1946 gave 5.73 Gm. total, with albumin 3.05 Gm. and globulin 2.68 Gm., per hundred cubic centimeters.

The blood urea level on May 23 was 24 mg. per hundred cubic centimeters.

Serum tests for psittacosis antigen by complement fixation test gave a negative reaction. Agglutination reactions were negative for typhoid, paratyphoid A and B and undulant fever antigens.

Course.—On the second hospital day of the patient marked conjunctivitis developed, and the dry cough noted on entry became severer. The lungs were resonant to percussion throughout, with fine crackling rales at the right base posteriorly. He was given an initial dose of 4 Gm. sulfadiazine, followed by 1 Gm. every four hours for four days. During this period the pulmonary signs became more pronounced and the patient remained febrile. On the fourth hospital day wheezes and rales were heard over the entire chest. The patient became extremely cyanotic and dyspneic. Theophylline ethylenediamine (0.5 Gm.) was given intravenously, without noticeable relief.

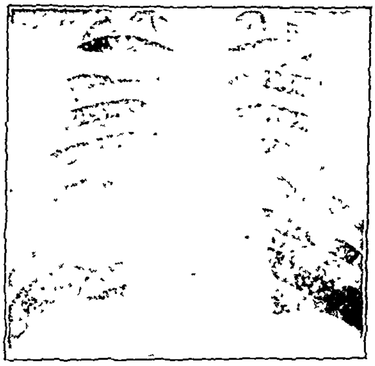

Fig. 3.—Partial clearing of the pulmonary densities.

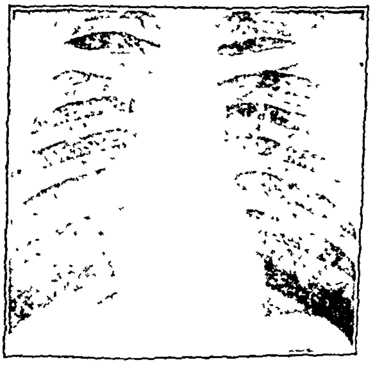

Fig. 4.—Decided regression of the pulmonary densities.

There were visible in the roentgenogram of the chest taken at this time diffuse, finely nodular infiltrations throughout both lung fields. These were more definite in the midportions and particularly about the hilar regions. The perihilar density was suggestive of pulmonary edema. Some increase in the size of the cardiac shadow was observed (fig. 2). The patient was placed in an oxygen tent for several days, which afforded him great relief, and was given 20,000 units of penicillin every three hours for five and one-half days, but his temperature remained elevated. On the eleventh hospital day he became subjectively well. The lesions of the skin were almost entirely healed. The lungs seemed clear by auscultation and percussion. On the thirteenth hospital day the mottled densities seen on the roentgenograms of the chest were still present, although less pronounced and slightly reticular in appearance. The slight cardiac enlargement persisted (fig. 3). On the same day the patient's temperature rose to 102 F., and he remained febrile for seven days more. Blood cultures made during this time were negative. Chest roentgenograms on the twenty-seventh hospital day revealed still further clearing of the pulmonary densities (fig. 4). On the twenty-eighth hospital day urinalysis revealed albumin (2 plus) and an occasional erythrocyte, although the patient seemed clinically well. He was discharged to private care and was not available for further follow-up.

Tables 1 and 2 show the course of cellular elements in the blood. It is of interest to note that, at the height of his pneumonia, the patient had a leukopenia with no increase in neutrophils but, rather, an increase in lymphocytes.

A roentgenogram of the chest on discharge revealed almost complete clearing of the lung fields and return of the cardiac shadow to its original configuration.

COMMENT

The chronologic association of roentgenograms of the chest with laboratory tests and with clinical signs and symptoms was made purposefully. Only minimal pulmonary densities were seen at first, despite symptoms. These persisted long after the signs and symptoms had disappeared. The degree of the pulmonary involvement coincided with the course of cutaneous manifestations. The diffuse patchy involvement shown and described in the literature was noted.[6] The increase in the size of the heart was also shown, with its return to the original size on regression of the pulmonary changes.

On the twenty-eighth hospital day there appeared clinical evidence of nephritis, which was not present before and which had been looked for during and shortly after the sulfadiazine therapy. Hematuria and albuminuria persisted thereafter and remained about the same. Excretory urography was done once and did not show any morphologic or functional abnormality.

Response to sulfadiazine or penicillin therapy by clinical improvement or lowering of temperature was lacking. There was later improvement in this regard without either of these therapeutic agents. No pathogenic bacteria could be recovered from the blood or from samples of sputum. These observations certainly do not favor belief in the presence of a concomitant or secondary bacterial infection. Bacterial infection in already diseased tissues was probably prevented by the use of sulfadiazine and penicillin. Reactions to agglutination tests helped to rule out at least one of the more frequent and one of the less frequent forms of virus pneumonia. Lack of facilities prevented the determination of antistreptolysin titer. All the changes observed were probably due to the chickenpox.

SUMMARY

A case of disseminated chickenpox with recovery is reported. Pneumonia and nephritis were present without any demonstrable pathogenic bacteria in the upper part of the respiratory tract or in the circulating blood.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following report. HOWARD A. CARTER, *Secretary.*

TRIBUTE TO THE MEMORY OF DR. EBEN J. CAREY

The Council on Physical Medicine of the American Medical Association records with deep sorrow the death of

Eben James Carey

When death came to Eben James Carey on the morning of June 5, 1947, the Council lost one of its most active and helpful members, and American medicine one of its respected teachers and research workers. Death was caused by acute infectious hepatitis.

Dr. Carey was born in Chicago on July 31, 1889. He was graduated from Rush Medical College, Chicago, in 1925 and served an internship at the Presbyterian Hospital in that city. He received the bachelor of science, master of science and doctor of science degrees from Creighton University in Omaha, where he taught for six years before coming to Marquette University in 1920. While at Marquette he was dean of medical students from 1921 to 1928, medical director of the Free Dispensary from 1924 to 1928 and chief of staff of the University Hospital from 1926 to 1928.

He was a fellow of the American Association for the Advancement of Science and the New York Academy of Medicine, a member of the Milwaukee Academy of Medicine, serving as its president in 1939 and 1940, Chicago Institute of Medicine, the American Association of Anatomists and formerly vice president of the Association of American Medical Colleges.

The Radiological Society of North America awarded him a gold medal in 1933 in recognition of his x-ray study of bone growth. He was chairman of the program committee of the Council on Scientific Work of the State Medical Society of Wisconsin, which in 1938 presented him with the Council award.

One of Dr. Carey's especial interests was the dissemination of scientific health information to the public; his work in this field was based on the conviction that museum exhibits can be interesting and practical without sacrificing accuracy. The success of the displays in the Hall of Science at Chicago's Century of Progress was largely due to the enthusiasm with which he planned the medical portions of the work and the eagerness with which he visited institutions, especially in Europe, in search of suggestions. His ability to rouse popular interest enabled him to advance the cause of physical medicine in Wisconsin perhaps more than any other individual there.

As a member of the Council on Physical Medicine he was able to make special contributions because of his interest in body mechanics, the details of kinesiology and especially the minutiae of the function of the vertebral column. In the last months of his life he was actively interested in interpreting the significance of atomic energy to the medicine of the future; he contributed a well considered report on that subject at the meeting of a committee of the Council on Dec. 12, 1946.

Members will miss Dr. Carey for the buoyant, cheerful effectiveness with which he went to work on the various problems of the Council.

SATURDAY, AUGUST 9, 1947

PROPAGANDA ACTIVITIES OF GOVERNMENT AGENCIES

In a report[1] to the House of Representatives it is charged that certain government agencies are using public funds in an improper manner for propaganda activities in support of a program of national compulsory health insurance. The agencies listed are the U. S. Public Health Service, Children's Bureau, Office of Education, U. S. Employment Service, Department of Agriculture and the Bureau of Research and Statistics of the Social Security Board.

On Dec. 10, 1945 the Surgeon General of the Public Health Service, Dr. Thomas Parran, wrote to all field men and staff operators of the Public Health Service throughout the country referring to the President's message to Congress, which urged enactment of a national health program. In this letter[2] Dr. Parran said "Every officer of the Public Health Service will wish to familiarize himself with the President's message and will be guided by its provision when making any public statement likely to be interpreted as representing the official views of the Public Health Service." Pursuant to this policy, according to the report, the public health service planned a series of conferences and "health workshops," so called, to be held in various states. It appears that full time government employees were sent, for a purpose, on these trips and that their traveling expenses cost the taxpayers nearly $5,000. This, the House committee found, was an unlawful use of federal funds, and the matter has been referred to the Department of Justice.

The "health workshop" held at Jamestown, N. D., Sept. 27-30, 1946 was attended by eighteen government employees who were away from their desks for a total of 126 man days. The chairman of this conference was Mayhew Derryberry, Ph.D., of the Public Health Service. The conference held at the University of Chicago to plan the propaganda campaign was attended by nine government employees and eleven representatives of labor organizations and the Farmer's Union. The "health workshop," held at St. Paul, was attended by eighty persons, including fifteen government employees. The leaders or "training officers" at the "health workshops" used instruction sheets on which the following topics were listed: (1) formation of pressure groups, (2) technics for the organization of citizen groups and (3) methods of bringing about group actions. The Public Health Service distributed to the invited delegates pamphlets in support of socialized medicine, published by government bureaus, the C. I. O., the A. F. of L. and the Physicians Forum, the latter said to be a propaganda agency for the Wagner-Murray-Dingell bill. The delegates thus indoctrinated were then given tests to determine their ability for leadership. It was interesting, a witness said, to note that when left to themselves the delegates were unable to think of any particular health problems in his state.

The House committee found that most of this literature, as distributed by the C. I. O., the A. F. of L., the Farmer's Union and the Physicians Forum originated in the Bureau of Research and Statistics of the Social Security Board, with which Mr. Isadore Falk is closely associated. Indeed, a member of his staff, Miss Margaret Klem, is said to have helped draft the Wagner-Murray-Dingell bill.

The testimony of Dr. Herman Hilleboe, then Assistant Surgeon General and now health officer of the state of New York, according to the committee report, reflected the spirit which dominates officials of the Public Health Service in the campaign to high pressure this legislation through Congress. Dr. Hilleboe was asked whether the literature prepared by the federal agencies discussed both sides of the question or was limited to material supporting President Truman's desire for a national health program. Dr. Hilleboe replied "We would naturally give emphasis to that, because that is why we are in government. Otherwise, we should get out of government." An attitude of intolerance toward honest discussion of the issue was shown also by another witness, Mr. Harry J. Becker of the Children's Bureau, who made speeches throughout the country in advocacy of the President's national health program. Mr. Becker was asked "Did you give both sides of the question of compulsory health insurance when you gave your discussions?" Mr. Becker replied "I don't know what you mean by both sides." His testimony before the House committee, it is said, typically disclosed how funds appropriated by Congress are diverted to propaganda favoring socialized medicine. The committee has evidence that the Bureau of Research and Statistics in the Social Security Board, of which Mr. Isadore Falk is the director, maintains close contact with movements for compulsory health insurance in other countries. Only last May Mr. Falk requested that Jacob Fisher, one of Mr. Falk's assistants, be sent to New Zealand at government expense to study compulsory health insurance programs. Jacob Fisher, by the way, is well known by the House Committee on Un-American Activities, and the committee expects later to present to Congress a detailed record of his activities.

---

[1] Third Intermediate Report of the Committee on Expenditures in the Executive Departments, House Report 786 of the First Session, 80th Congress, submitted July 2, 1947 to the Committee of the Whole House on the State of the Union.

[2] The Journal, Jan. 12, 1946, p. 84.

In the meantime the intermediate report of the House Committee on Expenditures in the Executive Departments is a sad reflection on the U. S. Public Health Service and some other government agencies involved. It should be emphasized that a public health service that is authorized to administer millions of dollars of public funds to carry on scientific medical research and that is constantly expanding its activities to reach the lives of more and more of our people should be kept free from such activities as are disclosed in this report. That is what this country expects of its Public Health Service.

ANURIA OF THERMAL BURNS

Hemoglobinuria is an early complication of severe burns; it results from the rapid destruction of red cells; hemoglobinemia is associated with consequent excretion of free hemoglobin in the urine. Shen and his co-workers[1] found gross hemoglobinuria in 9 patients and minimal hemoglobinuria in 2 among 40 patients of the Cocoanut Grove fire who had second and third degree thermal burns involving 15 to 65 per cent of the body area. Damaged renal function, according to Olson and Necheles,[2] is similar to that following hemolysis from incompatible blood transfusion, blackwater fever and other hemolytic diseases. The common factor in all these cases was intravascular hemolysis due to the sudden and rapid destruction of red cells or muscle cells. Ross[3] stresses that the escape of large quantities of hemoglobin from erythrocytes into the plasma is almost invariably followed by grave symptoms and frequently by death.

Olson and Necheles conducted animal experiments to determine the relative effectiveness of present methods of relief in burn anurias. Following experimental thermal burns, the abdomens of the animals were opened and each ureter was cannulated and connected to a sensitive drop recorder and counter which registered on a kymograph the urine excreted from each kidney. The severity of this experimental anuria could be correlated in most of their experiments with the degree of hemoglobinemia. They regarded, therefore, the amount of free hemoglobin in the plasma as a basis for comparing the therapeutic value of infusion fluids and diuretics. They found that plasma and saline solutions were the least effective infusion fluids for combating the anuria. They list the following solutions in increasing order of effectiveness: sodium lactate, 5 per cent dextrose in isotonic solution of three chlorides, 2 per cent urea in saline solution and 0.9 per cent saline solution with 0.87 per cent sodium bicarbonate. These solutions were effective in instances in which kidney damage was not great. Isotonic sodium sulfate, recommended originally by Maitland[4] for the treatment of the crush kidney, proved to be the most effective agent in combating the burn anuria. It has overcome anuria in all their experiments, including one of severe type in which the free plasma hemoglobin was over 4,000 mg. per hundred cubic centimeters. The concentration of free hemoglobin in the plasma was most effectively decreased by the use of sodium sulfate. While infusions of plasma gave an apparent reduction of plasma hemoglobin, this was demonstrated to be associated with the more prolonged diluting effect of the plasma.

The following substances had little diuretic effect when kidney impairment was great: mercuzanthin, aminophylline, thiamine, hydrochloride, ascorbic acid, nicotinic acid, vitamin B_2 and vitamin B_6. As to the danger of the use of isotonic sodium sulfate, Maitland has given in some of his cases as much as 8 liters during the first eleven days, with complete recovery. Olson and Necheles believe that it might be possible to give an initial injection of sodium sulfate to start the flow of urine and then to follow this with other diuretic agents.

Current Comment

FOLIC ACID IN BLOOD

Folic acid has been recognized as one of the vitamins of the B complex. Within the past few years it has been shown to be required for growth in the rat and for normal red cell production in the chick. Its beneficial effects in pernicious and other macrocytic anemias in man have been demonstrated,[1] and use of a microbiologic method of assay has revealed that whole blood of man and of cattle contains 2 micrograms of free folic acid per hundred cubic centimeters, whereas four to eight times as much is present in the whole blood of pigs, chickens and turkeys.[2] In all these species the plasma was found to contain less free folic acid than does the whole blood. When the blood was digested with the enzyme taka diastase, the folic acid conjugate was hydrolyzed with the release of large increments of the free vitamin, which in human blood amounted to forty to seventy times more than was originally present. Should it be demonstrated that the diet influences the blood concentration of folic acid, the adequacy of nutrition with respect to this important food factor can be demonstrated by this convenient and accurate type of blood analysis.

THE PREVENTION OF AIR BORNE STREPTOCOCCIC *INFECTION*

In a review of the transmission by air of certain infectious diseases Robertson[1] deals especially with air borne streptococcic infection as studied in the army during the war. The spread of hemolytic streptococci was traced by virtue of their characteristic growth on blood agar and their occurrence in distinct serologic types. Cultures of the air in army hospitals and barracks revealed definite association between certain types of air borne streptococci and infections due to those types. Infected patients and healthy carriers are the primary sources of air borne pathogenic streptococci; secondary reservoirs are built up by accumulations in bedding, clothing and floor dust, from which they spread into the air. Direct association has been demonstrated between sweeping floors and making beds and the numbers of hemolytic streptococci recovered from the air. The fact that in a few hours the environment might become heavily seeded with hemolytic streptococci led to special studies of the ways in which the carrier contaminates his surroundings. It was found that "the *largest numbers of streptococci were dispersed by* persons harboring these micro-organisms in their noses; and, since such persons have been found to be the principal agents in the spread of streptococcic disease, they are to be regarded as dangerous carriers." Blowing the nose, sneezing and handling the nose and mouth by the carrier are regarded as the principal ways of contaminating the patient's clothing, the bedding, the air, the floor and other horizontal surfaces. Oiling clothing and floors restrains greatly the spread of streptococci in the air from these secondary reservoirs. The studies of triethylene glycol vapors as means of controlling the aerial spread of respiratory infection "are as yet too few to more than indicate promise," but notable advance has certainly been made toward the prevention in civil as well as military practice of the spread of respiratory infections by hemolytic streptococci.

PUBLICATIONS OF THE COUNCIL ON PHARMACY AND CHEMISTRY

The publications of the Council on Pharmacy and Chemistry have long been used for pursuing rational therapeutics. New and Nonofficial Remedies, Useful Drugs and the Epitome of the U. S. P. and N. F. are titles familiar to physicians and medical students, and their usefulness is well known. The frequent revisions of these books provide authoritative information on what is new and of proved value. These Council sponsored volumes have just undergone revision and are now available from the publisher, the J. B. Lippincott Company, Philadelphia. New and Nonofficial Remedies contains the most recent information on the drugs accepted by the Council as of Jan. 1, 1947. The book is revised annually. This year the format has been changed slightly to place descriptions, actions, uses and dosage, and accepted brands and dosage forms in one section, and the tests and standards in another section. The latter are arranged alphabetically, while the former are grouped, as they have been for the past few years, in twenty-five chapters, the first one entitled "Agents Used in Allergy" and the last one "Vitamins and Vitamin Preparations." Useful Drugs and the Epitome likewise have undergone thorough revision. The consensus on what is the best in modern drug therapy is reflected in these publications of the Council on Pharmacy and Chemistry.

DESOXYRIBONUCLEIC ACID AND BACTERIAL "MUTATIONS"

For a number of years bacteriologists have known that the rough or avirulent strain of pneumococcus can be changed to the smooth or virulent strain by a number of successive animal passages. This change from the R *to* the S *strain* also follows a single injection if a vaccine prepared from the S strain is injected along with the R *strain.*[1] When it is changed to the S strain an R strain may revert to the type of pneumococcus from which it was derived or, depending on conditions, may change to another type, the type from which the vaccine was prepared. Through the intermediate R forms, type II S pneumococcus has been changed successively to types III S, II S and IV S.[2] These changes also take place in vitro in suitable culture mediums. The substance causing this transformation has been isolated and shown by serologic, chemical and enzyme methods to be desoxyribonucleic acid; it is active in dilutions as high as 1 : 30,000. An amount of purified nucleic acid splitting enzyme prepared from pancreas, desoxyribonuclease, added to a reaction system in amounts as small as 0.0012 microgram per cubic centimeter, inactivates the transforming substance.[3] The desoxyribonucleic acid fractions obtained from the various types of pneumococci cannot be differentiated on a chemical or serologic basis. These fractions do differ, however, in that they cause change of R forms to different types, the types from which the fractions were obtained.[4] The change of R to S forms which results from successive animal passage may be due to the action of small amounts of the specific desoxyribonucleic acid. The heat labile inhibiting substance for these changes found in serum may be desoxyribonuclease. Investigators have refrained from calling these changes true genetic mutations. The action of the transforming substance has been compared with the action of a virus and also with the causative agent of some fowl tumors. As the differences in form of these bacteria are attributable to differences in genetic structure, the change from one form to another, it would seem, must be attributed to genetic mutation.[4]

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

Aug. 6, 1947.

Replacement for General Bradley as Veterans Chief

Gen Omar Bradley is slated to succeed General Eisenhower as army chief of staff following his six weeks tour of American outposts in Europe starting August 15 President Truman and his administration leaders are reported to be searching for a man to carry through Bradley reforms in the Veterans Administration, where he is now serving as administrator. Assisted by Major Gen Paul R. Hawley, chief medical director of the agency, General Bradley is credited with making valuable improvements in the medical and other departments Leading physicians and the larger medical schools now participate in the program The Veterans Administration has more than 200,000 employees Although Congress stressed economy in appropriations during the session just concluded, the agency will have $20,000,000 more than Mr. Truman requested for the medical and hospital departments However, the agency's administrative staff must be reduced

Study of Psychologic Aspect of Human Resources in Wartime

Dr. Vannevar Bush, chairman, Joint Research and Development Board, has announced formation of a committee on human resources to study the human element in modern warfare, particularly problems of psychology. On the committee are Donald C. Marquis, president, American Psychological Association; C. L Shartle, psychology department, Ohio State University; Frederick F. Stephan, sociology department, Cornell University; Samuel A Stouffer, social relations department, Harvard University; Major Gens. Fred L. Anderson and Raymond W. Bliss, and Col Fred C. Miller, U. S Army, A. H. Hausrath, Office of Naval Research; Rear Admiral J. W. Roper, U. S. Army, and Capt D. T. Eddy, U. S. Navy.

Senator Advocates Hospital Commemorating Booker T. Washington

Senator Revercomb, West Virginia, urged action on his proposal that a hospital for Negro war veterans be erected in Franklin County, Va, at the birthplace of Booker T Washington The Veterans Administration is stated to have opposed the plan on grounds that a hospital for Negro veterans should be near a Negro medical center.

Georgetown University Hospital Opened

The new Georgetown University Hospital has been opened to the public The new hospital increases patient capacity from 241 to 407 and replaces old cramped quarters with modern facilities For some time the institution has provided the only free medical care in the western limits of the Capital Since the Veterans Administration abandoned the Nevius tract in Arlington, Va, as a site for the projected veterans' hospital, the National Capital Park and Planning Commission has been studying other sites

Vice Admiral McIntire Heads National Group to Employ Handicapped

Vice Admiral Ross T. McIntire, former Surgeon General of the Navy, was elected president of the National Association for Employment of the Handicapped, succeeding Major General Graves B. Erskin, U. S Marine Corps, who returned to active duty. Dr. Merle E. Frampton, principal of the New York Institute for Education of the Blind, became vice president. Virgil Smirnow, assistant to the director of the B'nai B'rith vocational service bureau, was named executive secretary of the National Association of the Handicapped, Inc.

House and Senate Differ on Funds Allotted for Atomic Cancer Research

The House allocated $25,000,000 for cancer research to the Atomic Energy Commission, but a Senate spokesman indicated that the Senate would set a $5,000,000 limit for this purpose. The Congressional dispute over the amount of funds for cancer research arose during discussion of total funds for the agency. Chairman David Lilienthall and member L L Strauss said the commission had not asked for funds for this purpose and the House item came as a surprise Senators Reed of Kansas, Saltonstall of Massachusetts and Tydings of Maryland said they believed there might be overlapping in cancer research. The American Cancer Institute raised $13,000,000 for research through public contributions, and the National Cancer Institute received $14,000,000 from Congress. The commission is the only agency allowed to produce radioactive materials for cancer research, and some 60 institutions are being supplied The commission announced that Los Alamos, N. M., principal center for military applications of atomic energy, where the first A bomb was made, is now a permanent establishment.

Coming Medical Meetings

American Association of Medical Record Librarians, New York, Hotel Commodore, Sept 7-12 Mrs Adaline Hayden, 18 E. Division St, Chicago, Executive Secretary.

American Association of Obstetricians, Gynecologists and Abdominal Surgeons, Hot Springs, Va, The Homestead, Sept 4-6. Dr. James R Bloss, 418 Eleventh St, Huntington 1, W. Va, Secretary

American College of Surgeons, New York, Waldorf Astoria Hotel, Sept. 8-12. Dr Paul B Magnuson, 40 E Erie St, Chicago 11, Secretary.

American Congress of Physical Medicine, Minneapolis, Hotel Radisson, Sept. 2-6. Dr. Richard Kovacs, 2 E 88th St, New York 28, Secretary.

American Congress on Obstetrics and Gynecology, St Louis, Municipal Auditorium, Sept. 8-12 Mr. Karl S. Richardson, 24 West Ohio St, Chicago, Business Manager.

American Roentgen Ray Society, Atlantic City, Sept. 16-19. Dr. H. Dabney Kerr, University Hospitals, Iowa City, Secretary.

Colorado State Medical Society, Denver, Shirley Savoy Hotel, Sept 17-20. Mr Harvey T. Sethman, 1612 Tremont Place, Denver 2, Executive Secretary.

International Cancer Research Congress, St Louis, Hotel Jefferson, 2-7. Dr Axel N Arneson, 510 S Kingshighway, St Louis, Chairman Committee on Local Arrangements

International College of Surgeons, U. S Chapter, Chicago, Palmer House, Sept 29-Oct 2 Dr. Louis J. Gariepy, 16401 Grand River Ave, Detroit 27, Secretary.

Kentucky State Medical Association, Louisville, Sept 29-Oct 2 Dr P E Blackerby, 620 S Third St, Louisville 2, Secretary

Michigan State Medical Society, Grand Rapids, Pantlind Hotel, Sept 24-26 Dr L Fernald Foster, 2020 Olds Tower, Lansing 8, Secretary

Mississippi Valley Medical Society, Burlington, Iowa, Oct 1-3 Dr Harold Swanberg, 510 Maine St, Quincy, Ill, Secretary
Woolsey, 316 Atlas Bldg, Salt Lake City 1, Secretary

National Medical Association, Los Angeles, Aug 18-22 Dr. John T. Givens, 1108 Church Street, Norfolk 10, Va, Secretary

Nevada State Medical Association, Reno, Sept 4-6 Dr Moreton J. Thorpe, 17 N. Virginia St, Reno, Secretary

Oregon State Medical Society, Portland, Sept 4-6 Dr Thomas S Saunders, 1020 S W. Taylor St, Portland 5, Secretary

Pennsylvania, Medical Society of the State of, Pittsburgh, Hotel William Penn, Sept 15-18 Dr Walter F. Donaldson, 500 Penn Avenue, Pittsburgh 22, Secretary

Southeastern Dermatological Association, Knoxville, Tenn, Hotel Andrew Johnson, Aug 31. Dr A H Lancaster, 608 W Main Ave, Knoxville, Secretary

Utah State Medical Association, Salt Lake City, Sept 11-13 Dr Ray T. Woolsey, 316 Atlas Bldg, Salt Lake City 1, Secretary

Vermont State Medical Society, Burlington, Hotel Vermont, Oct 1-3 Dr Theodore H Harwood, 128 Merchants Row, Rutland, Secretary

Washington State Medical Association, Seattle, Olympic Hotel, Sept 28-Oct 1 Dr Harold E Nichols, 327 Cobb Building, Seattle, Secretary

Western New York and Ontario Urological Society, Saranac, N Y, Saranac Inn, Sept. 3-6. Dr. Albert M. Crance, 525 S Main St, Geneva, N Y, Secretary.

World Medical Association, Paris, France, Sept 17-20 Dr Charles Hill, B M A House, Tavistock Sq, London, W C 1, England, and Dr. P Cibrie, 60 boulevard de Latour Maubourg, Paris 7e, France, Joint Secretaries

Bureau of Information

LOCATION OF PHYSICIANS

Virginia Shuler
Chicago

This is the seventh of a series of charts showing the trend in locations of physicians from April 1946 to January 1947.

"Regarding the distribution of physicians for Georgia, it must be remembered this state is largely rural and that we have 159 counties. To say that a county has only one or perhaps as many as two physicians does not mean the people of our state are suffering for the want of medical care. Indeed, a survey of seventeen counties by the Medical Association of Georgia in cooperation with the United States Public Health Service, before the war, indicated that only two persons had failed to obtain the services of a physician when they sought such services, and one of these persons stated his physician was ill and was unable to respond to the call.

"Georgia sent more than 600 physicians to the war. During this period the people of our state cooperated with the profession and there is no record of any patient really suffering for the want of medical care. Many of these physicians have returned to their practices, and conditions for the state as a whole are improving daily. A number of new hospitals have been built and equipped and others are in the planning for the future medical and hospital care of our people. All of this will no doubt add to the general good health of our people."

Dr. Edgar D. Shanks,
Secretary-Treasurer,
Medical Association of Georgia,
478 Peachtree Street N.E.,
Atlanta, Georgia.

"Distribution of physicians is improving, although there yet remain areas in need of them. The largest centers of population have been fortunate in adding to their total of practitioners, and some of the smaller centers have been provided for also."

Dr. Douglas L. Cannon, Secretary,
The Medical Association of the State of Alabama,
519 Dexter Avenue, Montgomery.

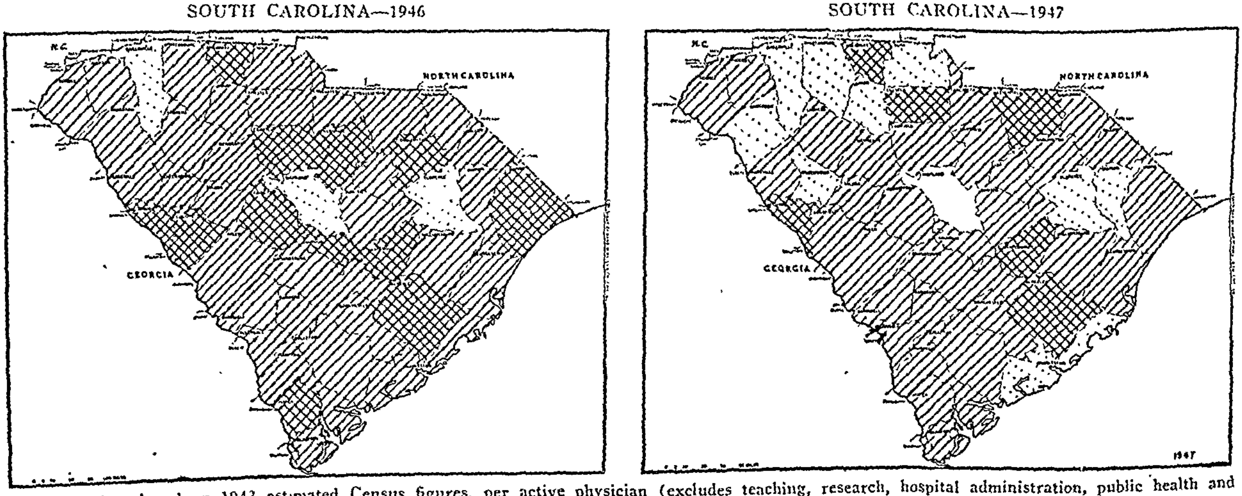
SOUTH CAROLINA



SOUTH CAROLINA—1946

SOUTH CAROLINA—1947

Population, based on 1943 estimated Census figures, per active physician (excludes teaching, research, hospital administration, public health and state hospitals) by county.

Key: Physician-population ratio by county: plain area 1-999, dotted area 1,000-1,499, striped area 1,500-2,999, checked area 3,000 and over, solid black area no doctor.

"Generally speaking, South Carolina is probably as well off for physicians as she was before the war. Most of the larger communities appear to be cared for fairly satisfactorily. There is still a need in the rural areas in South Carolina, as in other states, for more physicians. A surprising number of men coming back from the services are going into general practice. Our greatest need at the present time is for more physicians for rural areas and for the colored population."

JULIAN P. PRICE, M.D., Secretary,
South Carolina Medical Association,
Florence, S. C.

GOVERNMENT SERVICES

NAVY

NEW NAVAL HOSPITAL

The cornerstone of the new U. S. Naval Hospital under construction near Beaufort, S. C., was laid with appropriate ceremonies to which the public was invited July 18. In attendance were a number of Congressmen who flew from Washington, also Rear Admirals L. T. DuBose, Commandant, Sixth Naval District, C. A. Swanson, Surgeon General of the Navy, and J. J. Manning, chief, Bureau of Yards and Docks, and Major General Franklin A. Hart, commanding general, Marine Corps Recruit Depot, Parris Island, S. C., also some state senators and representatives and mayors of nearby cities. During the ceremony Admiral Swanson placed papers in the cornerstone dating back to 1863 and comprising the first request for a naval hospital to be built in this area.

PHYSICIANS VISIT NAVAL AIR BASE

To gain first hand knowledge of the operation of a naval air base a group of physicians departed from Glenview, Ill., and certain points in Michigan on a Marine Corps air transport landing at Pensacola, Fla., in July, where they toured the naval headquarters as the guests of the commander, Capt. William Sinton. The party boarded the aircraft carrier *Wright*, Capt. W. K. Berner, U. S. Navy, in command, to spend two nights and a day in the Gulf of Mexico and take part in certain activities of the ship. The party comprised Rear Admiral F. L. Conklin (MC), U.S.N., of the Ninth Naval District, Drs. John B Youmans, dean, University of Illinois Medical School, and Granville A. Bennett, Chicago; Dr. A. C. Furstenberg, dean, and Bradley Patten, Ph.D., University of Michigan Medical School; Drs. Warren E. Forsythe, director, University of Michigan Health Service, and Charles S. Kennedy, member of the board of regents, University of Michigan; Drs. Carey P. McCord, medical director for the Chrysler Corporation, Grover C. Penberthy and Archibald D. McAlpine, all of Detroit; Dr. Joseph J. Furlong of Marquette University Medical School, Milwaukee, and Michael A. Gorman, Flint, Mich.

NAVY AWARDS AND COMMENDATIONS

Commander Sam A. Bassett

The Bronze Star Medal has been awarded to former Commander Sam A. Bassett (MC), U.S.N.R., now in civilian practice in St. Louis. The citation read as follows: "For meritorious service in connection with operations against the enemy during the period Sept. 12, 1944 to April 28, 1945, while serving as medical officer of an escort carrier. During this period he participated in five major amphibious operations. His resourcefulness, great skill in administering to the wounded, coolness, gallantry and devotion in the prosecution of his duties when under attack by enemy dive bombers, torpedo planes, suicide bombers and an overwhelmingly superior surface force were a tremendous inspiration to officers and men alike. He contributed materially to the success of these operations against the enemy, and his performance of duty was at all times of outstanding efficiency and in keeping with highest traditions of the naval service." Dr. Bassett graduated from Washington University School of Medicine, St. Louis, in 1931 and entered the military service in 1940.

VETERANS ADMINISTRATION

MEDICAL AND PSYCHIATRIC SOCIAL WORKERS NEEDED

Vacancies exist for medical and psychiatric social workers in Veterans Administration installations throughout the country. Qualified social workers may file application in Veterans Administration hospitals, regional offices and clinics throughout the United States. Civil Service commission information regarding these positions may be obtained from any first or second class post office also. The salaries range from $3,397.20 to $8,179.50.

NURSES WANTED FOR TUBERCULOSIS HOSPITALS

The Veterans Administration is endeavoring to recruit nurses for assignments to tuberculosis hospitals. A training center has been established at Oteen, N. C., for graduate and senior cadet nurses, where particular emphasis is placed on protective measures to prevent as far as possible the dissemination of tubercle bacilli. Nurses wishing to specialize in this kind of work or any other clinical field may earn salaries equivalent to those heretofore available only in the field of nursing administration. The salaries range from $2,644 to $6,000. Applications should be submitted to the VA branch office having jurisdiction over the territory where the nurse desires to work.

TRAVELING MENTAL CLINIC

In order to provide more adequate patient care and follow-up care, and to effect a more rapid turnover of hospital beds, the psychiatric division of the Veterans Administration is loping a pilot traveling mental hygiene clinic which will from the Veterans Administration hospital at Lyons, N. J. The clinic will function administratively under the regional office, with the hospital supplying the professional personnel.

PERSONAL

Dr. Joseph A. McMullin, San Diego, Calif., rear admiral, U. S. Navy, retired, has been appointed chief medical officer of the Michigan veterans facilities, Grand Rapids. Dr. McMullin, a graduate of Jefferson Medical College, Philadelphia, served many years in the medical corps of the navy. He was in charge of the naval hospital at Pearl Harbor prior to the war and a former member of the faculty of medicine of the University of the Philippines. Dr. Edmund Quirk of Detroit also has been appointed a member of the staff of the Michigan Veterans Facilities, Grand Rapids. Dr. Quirk, a graduate of Wayne University Medical School, served abroad during World War II and since returning to civilian life has been on the staff of the Detroit Receiving Hospital.

Dr. George L. Johnson, formerly manager of the Veterans Administration hospital at Tuscaloosa, Ala., and recently on the staff of the Veterans Administration hospital at Thomasville, Ga., has been appointed chief medical officer of the Alabama regional office, succeeding Dr. Harley B. Fisk, who goes to the Miami, Fla., office as chief regional medical officer. Dr. Johnson is a veteran of both world wars and has been with the Veterans Administration since 1919.

Dr. Jerome Karmiol, chief medical officer in the regional office, Miami, Fla, has resigned to enter private practice. Dr. Karmiol, who is said to have organized the Veterans Administration regional medical clinic in Miami, will continue to serve as a part time member of the clinic staff.

Dr. Francis J. Phillips has resigned as superintendent of the Morgan Heights Sanatorium, Marquette, Mich., to accept the position as surgical chief of the 1,000 bed veterans' hospital in Temple, Texas. Dr. Phillips served in Europe with the Army in the recent war as a flight surgeon.

PUBLIC HEALTH SERVICE

CANCER CONTROL PROGRAM EXPANDED

The U. S. Public Health Service has expanded its program for cancer control. In the fiscal year which began July 1 funds to the extent of $2,500,000 will be allotted for this purpose to state health agencies, according to the following formula, which is similar to the one used last year: 30 per cent on population, 30 per cent on financial need, 35 per cent on cancer mortality and 5 per cent on population density. Using this formula as a basis, the total allotment for the state of Alabama, for example, for the fiscal year for cancer grants in aid is $60,529, and for the state of New York $209,602. Payments to the states will be made quarterly. Up to 15 per cent of the funds may be used to cover the cost of administration of the general health program and services not directly identified as cancer, when such services support the cancer control program. If any state requires more than 15 per cent for this purpose and can justify such requirement in writing, exceptions may be made. The Surgeon General will report from time to time to the National Advisory Cancer Council on the progress of the program.

Up to $1,000,000 available for cancer control will be used to support special cancer programs, and official state agencies may qualify for funds in the special project program. Medical schools, hospitals and other health agencies may also receive grants. Such plans and requests under the special projects program must be submitted through state health departments. The special projects fund will be expended mainly for postgraduate training of clinicians, surgeons, pathologists, radiologists and others specializing in cancer work, for short term training courses for general practitioners and for coordinated and concentrated teaching of cancer in medical and dental schools.

Every effort will be made to cooperate with the American Cancer Society and with the various national professional societies with substantial interest in the cancer problem, and the Public Health Service will encourage state health agencies to cooperate with similar bodies in the development of programs at their level.

THE NATIONAL MENTAL HEALTH PROGRAM

The national mental health program authorized by Congress in 1946 was implemented on July 8 by an appropriation of seven and a half million dolars. The Surgeon General, U. S. Public Health Service, has announced that the program calls for activity in three major fields: (1) increased research into problems of mental health, (2) increased training of urgently needed personnel and (3) increased support and stimulation of state efforts to develop adequate mental health programs.

About $400,000 will be spent during the present fiscal year for research by providing grants-in-aid to universities, hospitals, laboratories and other public and private institutions and to qualified individuals. With these grants, twenty-five research projects will be conducted in biochemistry, neurophysiology, delinquency, child psychology, alcoholism, psychosomatic medicine, psychotherapy and shock therapy. The fund also provides research fellowships in fields related to mental health, of which fourteen have been awarded.

Over a million dollars will be spent for grants to public and other nonprofit institutions for the development and improvement of facilities for training mental health personnel. The grants include seventeen in psychiatry, sixteen in clinical psychology, nine in psychiatric social work and nine in psychiatric nursing. This fund will also provide for training stipends for seventy graduate students in psychiatry, forty-one in clinical psychology, forty in social work and fifty-eight in psychiatric nursing.

A sum of $3,000,000 is appropriated for grants-in-aid to states for local mental health programs. The goal of the Public Health Service in the grants to states program is the establishment by the states program of one outpatient mental health clinic for each hundred thousand of the population and the provision of services to sparsely settled and rural areas through traveling clinics. State programs and budgets are now being received and grants are being allocated as soon as the plans are reviewed and approved. In addition, it is planned to establish demonstration clinics operated by the Public Health Service, and inservice training programs and training institutes for general practitioners in several states. Personnel will be lent to the states on request to aid local programs.

The remainder of the funds appropriated will be used for field studies in mental hygiene and the operation of the two U. S. Public Health Service hospitals for drug addicts and the mentally ill at Lexington, Ky., and Fort Worth, Texas.

NATIONWIDE INVENTORY OF SANITATION NEEDS

The Sanitary Engineering Division of the U. S. Public Health Service has completed an inventory of sanitation needs throughout the country. Among the estimates made as a result of the inventory is that more than a hundred million people of our cities need improved water supply and disposal facilities, and that it would cost $7,834,581,000 to provide them. This is said to be the minimum which should be spent to reduce the incidence or potential incidence of such diseases as dysentery, diarrhea and typhoid. This inventory, the Public Health Service states, the most complete inventory of basic sanitation needs ever compiled for the nation, was made with the coöperation of health departments of every state and hundreds of county and city health departments. "The cost of obtaining the healthy environment essential to a national health program" is itemized state by state. Almost 40 per cent of the needed construction is now at least at the planning stage, according to the survey. More than 9 per cent of the needed sewerage facilities costing about $360,509,000 is ready for construction; an additional 24 per cent costing $908,048,000 is definitely planned. Almost 17 per cent of the needed water supply systems costing $381,829,000 is ready for immediate construction, and plans are in progress for an additional 27 per cent costing $612,111,000.

In towns of less than 1,000 population the needs exceed $100 per capita, while in cities of more than 100,000 population the needs exceed $80 per capita. In towns of intermediate size the cost is about $50 and in rural areas $40. The cost estimates take into account variations in economic status and in practices and policies of local communities.

FEDERAL AID FOR CONSTRUCTING MEDICAL FACILITIES

The construction of millions of dollars' worth of hospital and health facilities during the fiscal year 1948 will be possible under the appropriations act signed by the President on July 8, Thomas Parran, Surgeon General, U. S. Public Health Service, announced. Although no federal funds were directly appropriated, the act sets up a procedure which obligates the federal government to pay up to $75,000,000 as its share of approved hospital construction, bringing the potential combined total of federal, state and local funds to $225,000,000. States need not delay their hospital construction plans, since they now have assurance that any construction project approved by the Surgeon General creates a contractual obligation on the part of the federal government to meet its one-third share of the cost.

This legislation implements the construction phase of the Hospital Survey and Construction Act passed by Congress last year, authorizing the appropriation of 3 million dollars for survey and planning and 75 million dollars for construction annually for five years. Two and a quarter million dollars was appropriated last year to assist the states in surveying existing hospital facilities. The 75 million dollars just appropriated for the fiscal year 1948 is the first money to be made available for construction. Funds may be used for health centers, laboratories, clinics and other medical facilities, as well as for hospitals.

All states and territories, including the District of Columbia, are conducting inventories of their hospitals and health facilities. So far construction plans of Indiana, Mississippi and North Carolina have been approved, and it is expected that more than half of the states will have submitted their plans by fall.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

ARIZONA

Harlow Brooks Clinical Conference.—The eighth Harlow Brooks Memorial Navajo Clinical Conference will be held at Sage Memorial Hospital, Ganado, August 25-27. The scientific program will include discussions of numerous medical topics by speakers from various states.

CONNECTICUT

Dr. Thoms Appointed Head of Department.—Dr. Herbert Thoms, associate professor of obstetrics and gynecology, Yale University School of Medicine, has been appointed professor and chairman of the department. Dr. Thoms graduated from Yale University Medical School in 1910 and studied at Johns Hopkins Hospital, 1914-1915. He became an assistant in obstetrics and gynecology in 1915, an assistant in pathology, 1916-1917, and an associate clinical professor of obstetrics and gynecology 1925-1927, when he became associate professor. He has also served as curator of the Yale Medical Memorabilia and has been an associate in obstetrics and gynecology at Grace-New Haven Community Hospital University service.

Society Honors Fifty Year Practitioners.—A dinner in honor of six members of the local medical society who had completed fifty or more years in the practice of medicine was held May 28 in Danbury. The physicians were presented with commemorative bronze medals inscribed with the caduceus, the name of the Danbury Medical Society and, on the reverse side, the name and number of years of practice of each individual. The doctors so honored were William T. Bronson, William F. Gordon and the late Howard D. Moore, all of Danbury, Homer F. Moore, Bethel, Paul U. Sunderland and Frederic W. Wersebe, Washington. Dr. James R. Miller, Hartford, president of the Connecticut State Medical Society, attended the dinner.

FLORIDA

Personal.—Dr. J. Randolph Perdue, Miami, has been elected president of the South Atlantic Association of Obstetrics and Gynecology. The territory covered by this association includes Virginia, North Carolina, South Carolina, Georgia and Florida.

Short Course for General Practitioners.—About 100 physicians attended the fifteenth annual graduate short course designed especially for Florida's general practitioners in Jacksonville, June 23-28. The course was presented by the Department of Medicine of the University of Florida Graduate School in cooperation with the Florida Medical Association and the Florida State Board of Health. Among the physicians addressing the group were professors from Vanderbilt University School of Medicine, Nashville, Tenn.; Tulane University of Louisiana School of Medicine, New Orleans; Duke University School of Medicine, Durham, N. C.; Johns Hopkins University School of Medicine, Baltimore, and members of the U. S. Public Health Service.

ILLINOIS

Health Officer Appointed.—Dr. Dale E. Scholz, formerly of the Middletown, Conn., Health Department, has been appointed director of public health of the new Wabash-Lawrence Health Department. Dr. Scholz received his medical degree from the University of Rochester School of Medicine, Rochester, N. Y., and his public health degree from Columbia University College of Physicians and Surgeons, New York.

Celebrate Centennial of State Hospital.—The state hospital at Jacksonville celebrated on July 27 the one hundredth anniversary of its establishment as the first institution in Illinois for the care of the mentally ill. State officials and representatives of veterans' organizations participated in the program. Richard W. Rowe, state treasurer, representing Governor Green, spoke on "Illinois—the Humanitarian," and Dr. Winfred Overholser, Washington, D. C., president of the American Psychiatric Association, discussed "Jacksonville, 1847—Psychiatry Then and Now." Beginning as an institution that cared for 138 patients, today it has a resident patient population of 3,084.

Chicago

Appoint Toxicologist.—Dr. Carl C. Pfeiffer, head of the department of pharmacology, University of Illinois College of Medicine, Chicago, will serve as toxicologist of Cook County until further notice, Coroner Albert L. Brodie announced July 14, succeeding Dr. William D. McNally. Dr. Pfeiffer, it is said, will receive $1 a year. The Cook County arrangement with Dr. Pfeiffer is expected to be the forerunner of a state laboratory available to all Illinois coroners.

Society Extends Postgraduate Courses.—The Chicago Medical Society will sponsor two postgraduate courses to be held in Thorne Hall on the Northwestern University Campus this fall. A course on cardiovascular diseases will be given October 20-25 and one on gastroenterology October 27 to November 1, with authorities from Chicago and various parts of the United States teaching. Enrolment is limited to 100. Applications may be sent to the office of the Chicago Medical Society at once, accompanied with the fee of $50 for each course.

Open Treatment Center for Alcoholic Addicts.—The Chicago Welfare Department opened Portal House, 5059 Vincennes Avenue, June 28, to alcoholic addicts in the city's welfare department to rehabilitate persons on relief who are unable to hold jobs because of addiction to alcohol. Portal House will have a full scale rehabilitation program providing medical care and group and occupational therapy. Treatment will be for four weeks, with a one year follow-up of the patient's progress. Doctors from the University of Illinois and the Illinois Neuropsychiatric Institute staff the wards. Members of Alcoholics Anonymous are cooperating on the program.

Dr. Coggeshall Appointed Dean.—Dr. Lowell T. Coggeshall, Chicago, professor and chairman of the department of medicine at the University of Chicago Medical School, has been appointed dean of the division of biologic sciences at the university, succeeding R. Wendell Harrison, Ph.D., who has been appointed vice president of the university. The division includes the school of medicine. A graduate of Indiana University School of Medicine in 1928, Dr. Coggeshall served as assistant professor of medicine at the University of Chicago Hospital, 1928-1935. For the next five years he was a member of the staff for research on tropical diseases, International Health Division of the Rockefeller Foundation in New York. In 1940 he went to the University of Michigan as a professor of preventive medicine in the School of Public Health and in 1942 became chairman of the department of tropical diseases there. He was commissioned lieutenant commander in the United States Naval Reserve in January 1944 and was promoted to commander in March of that year.

Smallpox Vaccination.—The board of health, after learning that a waiter had come down with smallpox soon after leaving Chicago, set up four vaccination centers in the area of the waiter's residence July 25 and quarantined possible sources of infection. The vaccination of residents of the square mile area of contact will continue for sixteen days. The health department assigned twenty-five doctors and nurses to work with the ambulances and three public clinics. Dr. Herman N. Bundesen, president, Chicago Board of Health, closed the commissary when he learned that the waiter had loaded food onto a train and ordered fifty commissary employees vaccinated immediately. He advised that the commissary of the Fred Harvey System supplying materials to the Santa Fe railroad is under quarantine with fifteen of its employees. The patient, who had prodromal symptoms for three days previous to leaving Chicago, was taken from the train at Clovis, N. M., when he became ill. Los Angeles health authorities boarded the Santa Fe train at San Bernardino to vaccinate the 138 passengers and crew members or place them under fourteen day quarantine. This patient had never been vaccinated.

INDIANA

Special Automobile License Plates.—The director of the state bureau of motor vehicles, H. Dale Brown, has announced that special license plates will be issued to Indiana physicians next year. The plates will carry the initials M.D. and will be numbered 1 to 4000. According to Mr. Brown, they are intended to expedite the work of physicians en route to emergency cases.

New Board of Health Building.—Plans for a new state board of health building have been approved by the state board health. The four story structure will contain a laboratory, office space and facilities to carry out the state public health program. There will be an auditorium with 136 seats and additional space for temporary seats and exhibits. The present quarters of the board of health will be turned over to Indiana University for laboratories and administrative offices.

LOUISIANA

Head of Preventive Medicine Department.—Dr. Robert L. Simmons, Meridian, Miss., became head of the department of preventive medicine and public health at Louisiana State University School of Medicine, New Orleans, August 1. Dr. Simmons, a graduate in public health of Louisiana State University School of Medicine, 1937, has been director of the Lauderdale County Health Department in Mississippi.

New Orleans-Metairie Hospital Foundation — The Metairie Hospital and the New Orleans-Metairie Hospital Foundation have opened a one story brick building in central Metairie to provide medical and hospital care for certain indigent cases that are recommended by the civic, church and other groups in Metairie. Facilities are available to all qualified licensed physicians in Louisiana. In addition to the regular hospital staff, there will be an open staff membership The facilities comprise emergency and operating rooms, delivery room, x-ray and fluoroscopic equipment, laboratory and pharmacy. There are 22 semiprivate beds and 8 bassinets. The director of the hospital is Dr. William K. Gauthier. The New Orleans-Metairie Hospital Foundation was organized by a group of business and professional men for the purpose of providing hospital facilities in this area.

MASSACHUSETTS

Discontinue Distribution of Toxin-Antitoxin. — The public health council of the commonwealth of Massachusetts discontinued the distribution of toxin-antitoxin on June 30 in accordance with recommendations of the National Institute of Health and authorities on diphtheria immunization. The opinion was that toxin-antitoxin mixtures should be entirely replaced by diphtheria toxoid for diphtheria immunization.

Woman Chemist to Receive Medal.—Mary L. Sherrill, Ph.D., head of the department of chemistry, Mount Holyoke College, South Hadley, will receive the Francis P. Garvan medal honoring women in chemistry at the national meeting of the American Chemical Society in New York, September 15-19. During the war Dr. Sherrill conducted investigations of antimalarial compounds at Mount Holyoke for the government. The Garvan medal was established in 1938 after the death of Mr. Garvan, philanthropist and lawyer, noted for his contributions for the advancement of chemistry.

MICHIGAN

State Medical Meeting.—The eighty-second annual session of the Michigan State Medical Society will be held at the Pantlind Hotel, Grand Rapids, September 23-26, under the presidency of Dr. William A. Hyland, Grand Rapids. Seven general assemblies, twelve section meetings and twenty-three discussion conferences are on the program. The out of state speakers include:

Allen O. Whipple, New York, Early Diagnosis of Pancreatic and Ampullary Growths, with an Evaluation of Surgical Therapy.
Andrew C. Ivy, Chicago, Diagnosis of Jaundice from a Therapeutic Point of View.
Wendell G. Scott, St. Louis, Investigation of Low Back Pain by Radiographic Methods.
Louis Schwartz, Washington, D. C., Diagnosis, Prevention and Treatment of Occupational Dermatitis.
Clifford B. Lull, Philadelphia, Changes and Improvements in Obstetric Practice During the Past Twenty-Five Years.
Frederic E. B. Foley, St. Paul, The Part of the General Practitioner in the Management of Vesical Neck Obstruction.
Harry Gold, New York, Management of the Failing Heart.
Russell L. Cecil, New York, Chronic Arthritis.
George M. Curtis, Columbus, Ohio, Surgery of the Spleen.
Alex D. Campbell, Montreal, Certain Aspects of Vaginal Surgery.
John R. Lindsay, Chicago, Vertigo: Differential Diagnosis and Treatment.
Ralph V. Platou, New Orleans, The Tuberculous Child.
Reynold A. Jensen, Minneapolis, The Doctor and the Child.
Claude F. Dixon, Rochester, Minn., Carcinoma of the Colon and Its Management.
Robert H. Williams, Boston, Comparison of Clinical and Physical Methods of Treating Thyrotoxicosis.
Cecil S. O'Brien, Iowa City, Senile Cataract from the Standpoint of the General Practitioner.
Frank E. Whitacre, Memphis, Tenn., Diagnosis and Treatment of Ectopic Pregnancy.
Michael E. DeBakey, New Orleans, Therapeutic Application of Hemometacinesis in Peripheral Vascular Disturbances.
Paul A. O'Leary, Rochester, Minn., Penicillin in Treatment of Syphilis in General Practice.
L. Emmett Holt Jr., New York, Treatment of Infantile Diarrhea.
Russell L. Haden, Cleveland, Gout.
Joseph D. Aronson, Philadelphia, BCG Vaccine in the Control of Tuberculosis.
Stuart W. Harrington, Rochester, Minn., Cancer of Breast.
Clement A. Smith, Boston, Potentialities and Limitations of Prenatal Pediatrics.
Alan R. Moritz, Boston, Medical-Legal Pathology.
W. Wayne Babcock, Philadelphia, Closure of Abdominal Fistula.
Wallace E. Herrell, Rochester, Minn., Present Status of Sulfonamide and Antibiotic Therapy.

The Women's Auxiliary will present a social and business program at the time of the scientific sessions.

Annual Meeting of Society for Crippled Children.—The Michigan Society for Crippled Children and Adults, Inc., will hold its sixth annual meeting in Marquette, August 10-11. Among the speakers will be Dr. Meyer A. Perlstein, director of the therapeutic nursery in Michael Reese Hospital, Chicago, who will lecture on the medical aspects of cerebral palsy and hold a demonstration clinic; Dr. L. Fernald Foster, Bay City, who will lecture on the Michigan rheumatic fever and cardiac program, and Dr. Moses Cooperstock, Marquette, who will speak on rheumatic fever.

NEW JERSEY

Personal.—Dr. Edward Guion, Northfield, has retired as superintendent and medical director of the board of free holders of Atlantic County Hospital for Mental Diseases, and Atlantic County Hospital (Alms House). Dr. Guion, who was honored at testimonial dinners by both hospitals, will resume the private practice of psychiatry in Pleasantville and will retain his membership on the psychiatric staffs of the Atlantic City Hospital and Atlantic County Hospital for Tuberculous Diseases, Northfield.

Physicians' Post Organized.—Formation of a physicians' post (445) of the American Legion, limited to members of the medical profession and reported to be one of the few units in the country, will be established September 27. Membership is opened to any American physician regardless of creed, race or color who had active duty in the army, navy or public health service during either world war and who was honorably separated from the service. The temporary commander is Dr. Ulysses M. Frank, Newark.

NEW YORK

Appointed Health Officer.—Dr. Frank E. Coughlin, Troy, temporarily serving as Rensselaer County chief medical officer, has been named permanent county commissioner of health to serve six years, effective June 1. Dr. Coughlin since last November has been in charge of the organization of the county health bureau under which the health service of Troy, Rensselaer, Hoosick Falls and various communities in the county were merged into a single county health bureau. This bureau has served as a pattern for other New York State counties which have inaugurated similar programs. Dr. Coughlin served as state district health officer prior to his temporary appointment and had been granted a year's leave of absence to organize the county health bureau. He resigned from the state health department to assume his new duties.

Postgraduate Instruction. — The Council Committee of Public Health and Education of the Medical Society of the State of New York in cooperation with the New York State Department of Health has arranged the following postgraduate courses for the Orange County Medical Society at the court house in Goshen at 8:30 p. m.:

September 9: Dr. Paul Reznikoff, associate professor of clinical medicine, Cornell University Medical College, New York, "Diagnosis and Treatment of Anemia."
September 30: Dr. Kurt Lange, assistant clinical professor of medicine, New York Medical College, Flower and Fifth Avenue Hospitals, New York, "Peripheral Vascular Diseases."
November 11: Dr. Edward F. Hartung, assistant clinical professor of medicine, Columbia University College of Physicians and Surgeons, New York, "Diagnosis and Treatment of Low Back Pain from the General Practitioner's Point of View."

New York City

Antiragweed Drive.—The city health department's antiragweed drive for the relief of hay fever sufferers will continue until mid-August. Ragweed is being sprayed with the chemical which destroys it before it gets to the pollen bearing stage. An unusually heavy growth has been reported this year in areas that were unsprayed last season. This year over 1,000 acres of ragweed has been destroyed in this way by the department of sanitation, the parks department and the health department.

New Research Laboratory.—Mutual Life Insurance Company of New York has agreed to finance the construction of a new $3,000,000 laboratory for the Sterling Winthrop Research Institute at East Greenbush, which will be leased back to Sterling Drug Company for thirty years with the tenant having the privilege of renewing the lease for six successive terms of ten years each. The four story laboratory will be divided into wings for chemical and biologic research and for administration and a library. The research wings will contain individual laboratory units, rooms for photography, x-ray and extreme temperature testing, as well as a pilot development plant. Dr. Maurice L. Tainter, Albany, director of the institute, said that the new laboratories will extend research into penicillin-like compounds, antibiotics, sulfonamide drugs, antimalarials, veterinary products, barbiturates, amino acids, streptomycin and other therapeutic preparations. Tropical medicine will be emphasized.

New Department of Psychiatry.—An independent department of psychiatry under the direction of Dr. Howard W. Potter has been announced by Long Island College of Medicine. The college announced also the appointment of Dr. Robert F. Barber, professor of clinical surgery since 1931, as emeritus professor. Heretofore the teaching of psychiatry has been conducted in cooperation with neurology. Dr. Potter received his medical degree from Columbia University College of Physicians and Surgeons, 1913. After serving in hospitals in New Jersey and New York he became director of research at the Letchworth Foundation, Thiells, in 1921 and was assistant director, New York State Psychiatric Institute and Hospital, from 1929 to 1934; also clinical professor of psychiatry at Columbia University College of Physicians and Surgeons and more recently professor of clinical psychiatry at Long Island College of Medicine. He was president of the American Association on Mental Deficiency in 1934.

Columbia to Provide Training in Rural Medicine.—The affiliation, effective at once, between Columbia University College of Physicians and Surgeons and the Mary Imogene Bassett Hospital in Cooperstown has been announced. Columbia expects to "contribute to the problem of training physicians for medical practice in small and rural communities and for better distribution of positions." The affiliation will "strengthen further the professional activities of the hospital through a stimulation and development of the professional staff in relation to undergraduate medical instruction and the training of interns and hospital residents." Facilities will be made available at the hospital for undergraduate medical education of students of the university.

OHIO

Dr. Porterfield Appointed State Health Director.—Dr. John D. Porterfield III, Columbus, has been appointed state health director, succeeding Dr. Roger Heering, Columbus (THE JOURNAL, July 5, p. 908). Dr. Porterfield, a graduate of Rush Medical College, Chicago, 1938, has been with the U. S. Public Health Service.

Appoint Director of Anesthesia.—Dr. Jacob J. Jacoby has been appointed associate professor of surgery and director of the division of anesthesia at the Starling-Loving University Hospital, Ohio State University, Columbus. Dr. Jacoby graduated in medicine at the University of Minnesota and has been serving as a research associate and assistant professor in anesthesia at the University of Chicago, where he has just received the degree of doctor of philosophy in pharmacology and anesthesia. He succeeds Dr. Norris E. Lenahan, who resigned April 30.

Drs. Culler and Barnes Appointed Department Heads.—Dr. Arthur M. Culler, member of the ophthalmology department of Ohio State University College of Medicine, Columbus, has been appointed chairman of the department, succeeding the late Dr. Albert D. Frost, who died Nov. 15, 1945. Dr. Culler received his medical degree at the University of Michigan Medical School, Ann Arbor, 1926, where he served as an instructor in ophthalmology from 1928 to 1930. Dr. Allan C. Barnes has been appointed head of the department of obstetrics and gynecology, succeeding Dr. Philip J. Reel, who has been acting part time chairman of the department. Dr. Barnes, who has been associate professor of obstetrics and gynecology for the past two years, received his medical degree at the University of Pennsylvania School of Medicine, Philadelphia, 1937, and his master's degree in obstetrics and gynecology from the University of Michigan Graduate School, Ann Arbor. Prior to entering the army in 1942 he was an instructor at the University of Michigan Medical School.

PENNSYLVANIA

Hospital Survey and Construction Division.—The governor signed legislation establishing a new Division of Hospital Survey and Construction in the State Department of Welfare July 7, thus opening the way for Pennsylvania's participation in the federal hospital improvement program. As in various other states, the agency is authorized to inventory existing hospitals, to survey the need for construction of new health facilities and to develop and administer a state plan for the construction of public and other nonprofit hospitals.

Philadelphia

Research on Poliomyelitis.—A grant of $106,000 to the University of Pennsylvania for a five year study of infantile paralysis has been made by the National Foundation for Infantile Paralysis. Detlev W. Bronk, Ph.D., director of the university's Johnson Research Foundation, will direct the research, which will investigate the metabolic process of nerve cells and how they are modified by the infantile paralysis virus. He will be assisted by Martin Larrabee, Ph.D., Frank Brink Jr., Ph.D., Thomas F. Anderson, Ph.D., and Philip W. Davies.

Pennsylvania Reorganizes Department of Medicine.—The University of Pennsylvania School of Medicine has announced a reorganization of its department of medicine and the appointment of a new department head. Dr. Francis C. Wood, Philadelphia, formerly assistant professor in medicine, is the new department head, succeeding Dr. O. H. Perry Pepper, Philadelphia, who wished to be relieved of administrative duties. Dr. Pepper has served the department for more than thirty years and will continue to teach and practice in the University Hospital until his retirement. Dr. Wood has been associated with the School of Medicine and Hospital since his graduation in 1926. During World War II he served in the Twentieth General Hospital. Drs. T. Grier Miller, Truman G. Schnabel and Charles C. Wolferth were named to full professorships in medicine. Dr. Miller, a graduate of the University of Pennsylvania School of Medicine, Philadelphia, 1911, is president of the Philadelphia County Medical Society. Dr. Schnabel, a graduate of the university in 1911, has been professor of clinical medicine and head of the university's teaching in medicine at the Philadelphia General Hospital. Dr. Wolferth, who graduated in 1912, is president of the Edward B. Robinette Foundation.

TENNESSEE

State Medical Election.—At the annual meeting of the Tennessee State Medical Association last April Drs. Franklin B. Bogart, Chattanooga, became president, Harley W. Qualls, Memphis, was made president-elect and William M. Hardy, Nashville, secretary-editor.

Dr. Aycock Returns to Tennessee.—Dr. George F. Aycock, after thirty years with the Army Medical Corps, has returned to his native state to take up the direction of the tuberculosis program at the University of Tennessee Hospital, Knoxville. The expanded tuberculosis program primarily will benefit the 7,500 students attending the University of Tennessee. Dr. Aycock recently retired from the Medical Corps as a colonel after many years of work in tuberculosis and diseases of the chest.

WEST VIRGINIA

New Superintendent of State Hospital.—Dr. Edward F. Reaser, Huntington, has been appointed superintendent of Huntington State Hospital, effective August 1, to succeed Dr. Charles T. Taylor, who has served as superintendent since 1933. Dr. Reaser is chief psychiatrist in charge of the mental hygiene clinic at the Veterans Administration regional office in Huntington. Previously he was assistant superintendent at Huntington State Hospital, resigning in November 1947 to accept the position with the Veterans Administration. A native of Glenville, he graduated at the Medical College of Virginia, Richmond, in 1930 and was on the medical staff at Pilgrim State Hospital, Brentwood, N. Y., when appointed assistant superintendent at the Huntington institution. He is a specialist certified by the American Board of Psychiatry and Neurology and a member of the American Psychiatric Association and the Medical Society of St. Elizabeth's Hospital.

WISCONSIN

Dr. Bowman Retires.—Dr. Frank F. Bowman on May 1 retired as health officer of the city of Madison, a position he has held for nineteen years. He was honored at a farewell dinner given by present and former employees of the city health department. Dr. Bowman, who is 74 years old, is a graduate of Rush Medical College, Chicago, 1897.

Symposium on Use of Isotopes.—The University of Wisconsin, Madison, will sponsor a symposium on the biologic applications of isotopes, September 10-13. The program includes:

David B. Sprinson, New York, Studies on Metabolism of Proteins.
Harland G. Wood, Ph.D., Cleveland, Studies on Metabolism of Carbohydrates.
Dr. Joseph G. Hamilton, San Francisco, Application of Tracer Research to Medicine.
Dr. Byron E. Hall, Rochester, Minn., Leukemia and Polycythemia.
Dr. Saul Hertz, Boston, Thyroid Disease.
William F. Bale, Ph.D., Rochester, N. Y., Health Hazards Involved in the Use of Radioactive Isotopes.

A panel discussion on Cancer will be held with Drs. Austin M. Brues, Chicago, Joseph G. Hamilton, San Francisco, Simeon T. Cantril, Seattle, and Paul S. Henshaw, Ph.D., Oak Ridge, Tenn., participating. Housing and meals will be provided at a cost of $5 a person daily. Reservations can be made and additional information obtained from Dr. Edwin C. Albright, Department of Medicine, 1300 University Avenue, Madison 6.

GENERAL

Scientists Go to Japan to Aid Research Plans.—The National Research Council has sent a group of American scientists to Japan to advise General Douglas MacArthur's staff on the democratization of scientific research. The group will consider plans submitted by Japanese scientific societies and make recommendations to the economic and scientific section of general headquarters in Tokyo. Led by Roger Adams, Ph.D., head of the department of chemistry, University of Illinois, other group members are Merrill K. Bennett, Ph.D., Stanford University, Palo Alto, Calif.; Dr. William D. Coolidge, director emeritus of research of the General Electric Company; William V. Houston, Ph.D., president of Rice Institute, Houston, Texas; William J. Robbins, Ph.D., director of the New York Botanical Garden, and Royal W. Sorensen, Sc.D., of the California Institute of Technology, Pasadena, Calif.

Research Fellowships Available.—The American College of Physicians announces that a limited number of fellowships in medicine will be available from July 1, 1948 to June 30, 1949 designed to provide an opportunity for research training either in the basic medical sciences or in the application of these sciences to clinical investigation. They are for the benefit of physicians who are in the early stages of their preparation for a teaching and investigative career in internal medicine. Assurance must be provided that the applicant will be acceptable in the laboratory or clinic of his choice and that he will be provided with the facilities necessary for the proper pursuit of his work. The stipend will be from $2,200 to $3,000. Application forms will be supplied on request to the American College of Physicians, 4200 Pine Street, Philadelphia 4, and must be submitted in duplicate not later than November 1. The American College of Physicians has announced its twenty-ninth annual session to be held in San Francisco, April 19-23, 1948 at the Civic Auditorium.

Graduate Course in Chest Diseases. — The American College of Chest Physicians is sponsoring a second annual postgraduate course in diseases of the chest to be held during the week of September 15-20 at the Municipal Tuberculosis Sanitarium, Chicago. The emphasis in this course, limited to thirty physicians, will be placed on the newer developments in diagnosis and treatment of diseases of the chest. Further information may be secured from the American College of Chest Physicians, 500 North Dearborn Street, Chicago 10.

American Congress on Obstetrics and Gynecology.—The third American Congress on Obstetrics and Gynecology will be held in St. Louis September 8-12 at the Municipal Auditorium. There will be a series of round table and panel discussions. The leaders of the discussions will be:

John L. Parks, Washington, D. C., Etiology of Abortion.
Ralph A. Reis, Chicago, Emotional Problems in Obstetrics and Gynecology.
Harold O. Jones, Chicago, Uterine Prolapse.
Samuel A. Cosgrove, Jersey City, N. J., Decentralization of Nurseries.
John Rock, Boston, Ovulation.
F. Bayard Carter, Durham, N. C., Prolonged Labor.
Joseph A. Hardy Jr., St. Louis, Treatment of Abortion.
Robert A. Kimbrough Jr., Philadelphia, chairman of panel on Cancer.
Emil Novak, Baltimore, Ovarian Tumors.
John I. Brewer, Chicago, Uterine Bleeding.
Raphael Kurzrok, New York, The Menopause.
Duncan E. Reid, Boston, Prolonged Labor.
Joseph L. Baer, Chicago, Work of Maternal Welfare Committees in the Larger Cities.
Newell W. Philpott, Montreal, Erythroblastosis.
Abraham F. Lash, Chicago, Geriatric Gynecology.
Edward D. Allen, Chicago, Endometriosis.
John M. Waugh, Rochester, Minn., Genital Relaxation:
Philip F. Williams, Philadelphia, Nutrition in Pregnancy.
William F. Mengert, Dallas, Texas, Prolonged Labor.
Edward A. Schumann, Philadelphia, chairman, panel on Cesarean Section.

Appointed to Secretariat of World Health Organization.—Two physicians have been added to the secretariat of the World Health Organization Interim Commission's headquarters office, New York City. Dr. William P. Forrest, D.P.H., has been appointed assistant director of the headquarters office and Dr. Chang K. Chu assistant director of the field services for China. Dr. Forrest was born in Glasgow, Scotland, and attended the Anderson College of Medicine and St. Mungo College of Medicine at Glasgow, the Royal College of Surgeons in Edinburgh and the University of Glasgow. He was chief medical officer with the United Nations Relief and Rehabilitation Administration's mission to the Ukrainian Soviet Socialist Republic. For two years he was medical officer of health and director of casualty services for the Notts County Council and the Mansfield and Warsop councils in England. Dr. Chu was born at Chekiang, China, and received his M.D. degree from the Peking Union Medical College and a degree of doctor of public health from Yale University Medical School. He has served as commissioner of the Kweichew Provincial Health Administration, director of the Public Health Personnel Training Institute at Chungking, China, and director of the National Institute of Health, Nanking, China. Dr. Chu was granted one year's leave from his post as director of the Chinese National Institute of Health to work with WHO.

Prevalence of Poliomyelitis.—Reports of cases of poliomyelitis for the periods indicated have been received from the division of public health methods, U. S. Public Health Service:

Marriages

E. Ross Jenney, Hollywood, Calif., to Mrs. Katalin Prohaszka of Budapest, Hungary, in Geneva, Switzerland, April 9.

Leldon W. Martin, Sebring, Fla., to Miss Clara Sheperd of Fairmount, Ga., in Miami April 27.

Clifford James Tichenor, Washington, D. C., to Miss Irene Mathilda Kruka at Cincinnati June 7.

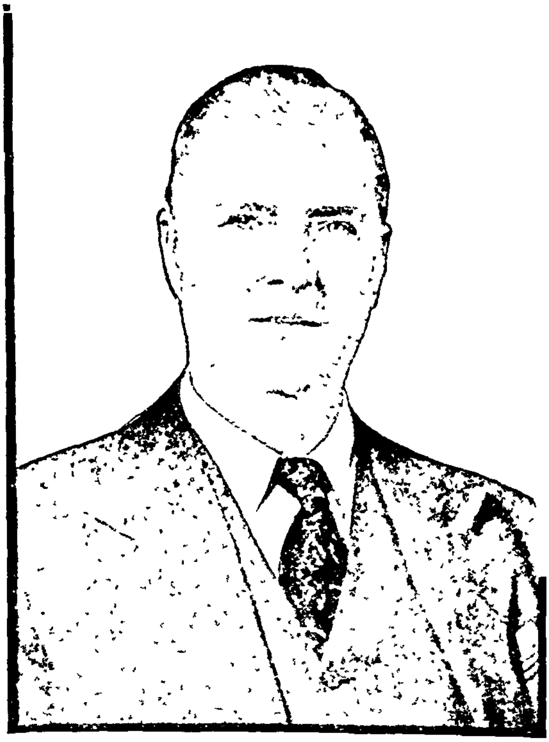
Harold M. Jesurun to Miss Lolin Lopez Pinero, both of San Juan, Puerto Rico, May 17.

Willard Ellsworth to Miss Margaret McQueeney, both of New York, Dec. 28, 1946.

Golda Fischer, San Francisco, to Professor M. A. Joslyn of Berkeley, Calif., April 20.

Deaths

Charles Wesley Roberts ⊕ Atlanta, Ga., a member of the Board of Trustees of the American Medical Association, died July 28, aged 63. Dr. Roberts was born in Nicholls, Ga., Dec. 13, 1883, and graduated at the University of Maryland School of Medicine, Baltimore, in 1906. He received a certificate of honor for his excellence in the examinations for his medical degree and later served as resident surgeon at the University Hospital. Dr. Roberts began practicing medicine at Douglas, Ga., in 1908, where from 1911 to 1916 he operated a private hospital. On Jan. 1, 1917 he opened an office in Atlanta, where he was an instructor in surgery at Emory University School of Medicine from 1918 to 1920 and then was appointed associate in surgery, serving until 1945. He had long been active in the work of the American Medical Association, serving as a member of the House of Delegates from 1925 to 1928 and again from 1932 to 1941, and as a member of the Council on Industrial Health from 1937 to 1941, in which year he was elected a member of the Board of Trustees of the Association. In 1946 he was reelected to the Board for a second term of five years, and at the recent Atlantic City session he was appointed a member of the Executive Committee of the Board of Trustees. Dr. Roberts was formerly chairman of the section on industrial health of the Southern Medical Association, a past president of the Eleventh District Medical Society, the Chattahoochee Valley Medical Association and the Southeastern Surgical Congress. He was a member of the advisory council of the Georgia State Board of Health, medical adviser of the Industrial Commission of Georgia from 1921 to 1938 and in 1946 was appointed a member of the State Hospital Advisory Committee. He was a fellow of the American Association of Industrial Physicians and Surgeons and the American College of Surgeons, an attending surgeon at the Georgia Baptist, Crawford W. Long Memorial and Grady hospitals, and was a member of the Atlanta Kiwanis Club from 1921 to 1938. Dr. Roberts contributed much to the surgical literature and at the time of his death was a member of the advisory editorial board of the *Southern Surgeon.*



Charles Wesley Roberts
1883-1947

Francis Edward Harrington ⊕ Minneapolis; born in Norfolk, Va., June 19, 1879; George Washington University School of Medicine, Washington, D. C., 1904; clinical professor of preventive medicine and public health at the University of Minnesota Medical School; served as city health commissioner, member of the Hennepin County Sanatorium Commission, director of hygiene of Minneapolis schools and secretary-treasurer of the International Society of Medical Health Officers; formerly affiliated with the U. S. Public Health Service; at one time medical inspector of the District of Columbia, health officer of Cumberland, Md., and Jefferson County, Ala.; past president of the Minnesota Trudeau Medical Society and the Minnesota Public Health Association and third vice president of the American Public Health Association; fellow of the American College of Physicians; founder and director of the Lymanhurst Health Center; served as acting superintendent of the Minneapolis General Hospital; awarded honorary degree of doctor of laws by Gonzaga College; died in West Palm Beach, Fla., May 9, aged 67, of cerebral infarct and pulmonary edema.

William Robert Thompson, Fort Worth, Texas; born in Perdue Hill, Ala., Dec. 24, 1862; College of Physicians and Surgeons, Baltimore, 1888; member of the American Medical Association; fellow of the American College of Surgeons; past president of the Texas Ophthalmological and Otolaryngological Society and the Tarrant County Medical Society; member emeritus and member of the original board of trustees of t State Medical Association of Texas, serving as secretary of t board for thirty-seven years; at one time associate profess of diseases of the eye, ear, nose and throat, dean and profess of ophthalmology at the Fort Worth School of Medicine; f many years city councilman; mayor pro tem from 1933 to 193 chairman of the board from 1922 to 1927 at the City-Cour hospital, where he served as consultant to the staff; memb at one time vice chairman and later president of the staff St. Joseph's Hospital; oculist and aurist of the Texas a Pacific, Southern Pacific, Rock Island, Santa Fe, Missou Pacific and Fort Worth and Denver Railroads from 1900 1940; died May 1, aged 84, as the result of a fall.

James Pedersen ⊕ New York; born in New York Aug. 1 1864; College of Physicians and Surgeons, medical departme of Columbia College, New York, 1890; an Affiliate Fellow the American Medical Association; specialist certified by t American Board of Urology; member of the American Ass ciation of Genito-Urinary Surgeons, serving at one time president, and the American Urological Association; served associate professor of urology at the New York Post-Gradua Medical School and Hospital; instructor in genitourinary su gery at the University and Bell vue Hospital Medical College a professor of venereal diseases the University of Vermont Co lege of Medicine in Burlingto consulting genitourinary surge at the Englewood (N. J.) Ho pital and the Stamford (Conn Hospital; died in Wilton May 1 aged 82, of heart disease.

Arthur John Lomas, Balt more; born Sept. 17, 1879; M Gill University Faculty of Med cine, Montreal, Que., Canad 1902; served with the Roy Army Medical Corps and France with the Canadian Arm Medical Corps during Worl War I; during World War executive director of the eme gency medical service in t civilian defense system; served a surgeon in the U S. Publ Health Service reserve; at on time assistant director of th Johns Hopkins Hospital in Balt more and director of the Univer sity Hospital at Iowa City; fo sixteen years superintendent the University Hospital; adminis trative consultant to five Catholi hospitals in Maryland: Mercy St. Joseph's, Bon Secours and S Agnes hospitals, all of Baltimore and the Allegany Hospital Cumberland; died at his home Lutherville, Md., May 17, aged 6

Curtis Alban Evans ⊕ Mil waukee; born in 1879; Universit of Michigan Department of Medi cine and Surgery, Ann Arbo 1904; formerly professor of anatomy at the Wisconsin Colleg of Physicians and Surgeons; past president of the Milwauke Academy of Medicine; member of the Milwaukee Surgica Society; served in France during World War I; fellow of th American College of Surgeons; member of the founders grou of the American Board of Surgery; on the surgical staff o the Columbia Hospital; consulting surgeon, Johnston Emergenc and Children's hospitals; for many years chief of staff of th Milwaukee Hospital, where he died May 3, aged 68, of hear disease.

James Lee Wilson ⊕ South Bend, Ind.; born in Janes ville, Ill., Aug. 16, 1885; Rush Medical College, Chicago, 1912 fellow of the American College of Surgeons; member of the founders group of the American Board of Surgery; member of the American Association for the Study of Goiter; president of the park board; member of the advisory board and executive staff at St. Joseph Hospital; surgeon for the Childrens Dispensary and Hospital Association; chief of the surgical staff, member of the board of directors, advisory board and executive staff, Memorial Hospital, where he died May 11, aged 61, of coronary occlusion.

James Linn Adams, Van Nuys, Calif.; Missouri Medical College, St. Louis, 1886; died March 18, aged 87.

Sanford Bailey ⊕ Garden City, Kan.; Kentucky School of Medicine, Louisville, 1893; on the staff of St. Catherine's Hospital, where he died April 28, aged 75, of carcinoma of the pancreas.

William Dewey Balfour, Wailuku, Hawaii; Washington University School of Medicine, St. Louis, 1927; member of the American Medical Association; formerly vice president of the Territorial Association of Plantation Physicians; captain, National Guard, not on active duty; died April 13, aged 48.

Rose Anne Bebb ⊕ New York; University of Minnesota College of Medicine and Surgery, Minneapolis, 1897; affiliated with the Bellevue Hospital; died April 16.

Plumb Brown, Springfield, Mass.; the Hahnemann Medical College and Hospital, Chicago, 1892; died April 28, aged 78, of carcinoma of the intestine with metastasis.

Edwin Bunnell, Willows, Calif.; Medical Department of the University of California, San Francisco, 1894; died in the Woodland (Calif.) Clinic Hospital April 26, aged 77, of carcinoma of the right lung.

John Rollo Burr, South Bend, Ind.; Chicago Homeopathic Medical College, 1897; died in the Memorial Hospital April 4, aged 73, of cerebral hemorrhage and sarcoma of the rectum.

Russell Williams Chidsey, New Holland, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1890; served during the Spanish-American War; found dead April 25, aged 78.

Frances Cohen ⊕ New York; Cornell University Medical College, New York, 1900; formerly assistant director of educational hygiene for the city board of education and pediatrician in the department of health; served in the pediatric division of the Mount Sinai Hospital; died April 18, aged 73.

Ovee John Colwick, Durant, Okla.; Southwestern University Medical College, Dallas, Texas, 1906; member of the American Medical Association; died April 2, aged 66, of heart disease.

Max Davis, Boston; Harvard Medical School, Boston, 1925; diplomate of the National Board of Medical Examiners; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; fellow of the American College of Surgeons; assistant professor of gynecology and obstetrics at the Boston University School of Medicine; on the staffs of the Massachusetts Memorial and Beth Israel hospitals; died in Cambridge April 30, aged 46, of rheumatic heart disease.

Charles A. Dawson, Minden, Texas; Louisville (Ky.) Medical College, 1891; member of the American Medical Association; affiliated with the Henderson Memorial Hospital in Henderson; died April 26, aged 79, of diabetes mellitus.

Pasquale De Feo, Medford, Mass. (licensed in Massachusetts in 1905); died April 19, aged 72, of uremia.

Dell S. Edwards, Covington, Ky.; Woman's Medical College of Cincinnati, 1895; died April 24, aged 90, of heart disease.

Carl Hernfrid Fornell ⊕ New York; Harvard Medical School, Boston, 1914; specialist certified by the American Board of Otolaryngology; served during World War I; formerly medical director of the Hartford Accident and Indemnity Company; on the staff of the Manhattan Eye, Ear, Nose and Throat Hospital; died May 7, aged 60.

Joseph Foster ⊕ Santa Fe, N. M.; Western Pennsylvania Medical College, Pittsburgh, 1901; died April 21, aged 73, of carcinoma.

Charles Frederick Frankman, Greenville, Ohio; University of Michigan Medical School, Ann Arbor, 1928; affiliated with the Wayne Hospital; died April 25, aged 43, when struck by a train.

Maude Granger Furniss, Brookline, Mass.; Boston University School of Medicine, 1897; died April 14, aged 73, of chronic myocarditis.

Malcolm Brown Fyfe, Valparaiso, Ind.; Northwestern University Medical School, Chicago, 1903; member of the American Medical Association; served overseas during World War I; school physician at Valparaiso University; member of the city board of health; on the staff of the Porter Memorial Hospital; died May 11, aged 71, of rupture of an abdominal aneurysm.

Frederick Arthur Grossman, Wilmette, Ill.; Northwestern University Medical College, Chicago, 1897; served in the Coast Guard during World War I; died in the Illinois Central Hospital, Chicago, May 16, aged 76, of a hip fracture received in a fall.

William Hipp, Detroit; Detroit College of Medicine, 1906; member of the American Medical Association; died May 2, aged 69.

Arnold James Gelarie ⊕ Ossining, N. Y.; Thüringische Landesuniversität Medizinische Fakultät, Jena, Thuringia, Germany, 1910; member of the American Public Health Association and the American Association for the Advancement of Science and others; at one time bacteriologist with the public health service at the U. S. Quarantine Station, Port of New York; died May 7, aged 61.

Earl Ray Gibbs ⊕ Wilkinson, Ind.; Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1907; served during World War I; died in the Methodist Hospital, Indianapolis, May 13, aged 66, of carcinoma of the breast with metastases to the lung.

Jacob Benjamin Ginsburg, Boston; College of Physicians and Surgeons, Boston, 1920; died April 30, aged 65, of coronary occlusion.

Duke Marvin Godbey, Perryville, Ky.; Hospital College of Medicine, Louisville, 1905; member of the American Medical Association; died May 5, aged 68, of cerebral hemorrhage.

Orren Pakenham Goodwin, Ruston, La.; born in Longstaw, La., Nov. 18, 1881; Baylor University College of Medicine, Dallas, 1913; formerly affiliated with the Indian Service; served overseas during World War I; lieutenant colonel, medical reserve corps, not on active duty; served on the staffs of Veterans Administration hospitals in various places; formerly on the staffs of the State Hospital in Pineville and State Hospital in Little Rock; died in the Veterans Administration Hospital in Alexandria, April 26, aged 65, of heart disease.

John Monroe Gray, Joplin, Mo.; St. Louis College of Physicians and Surgeons, 1899; member of the American Medical Association; Spanish-American War veteran; on the staffs of St. John's and Freeman hospitals; died May 2, aged 73, of chronic myocarditis.

Angelina G. Hamilton, Anna, Ill.; the Hahnemann Medical College and Hospital, Chicago, 1897; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1908; affiliated with the Anna State Hospital; died in Port Huron, Mich., April 30, aged 74, of coronary thrombosis.

John E. Hetherington ⊕ Grand Forks, N. D.; Jefferson Medical College of Philadelphia, 1909; served as a member of the state medical board; on the staff of the Deaconess Hospital; died May 9, aged 62, of arteriosclerosis and cardiac failure.

Frank Wheeler Hornbrook, Chevy Chase, Md.; Harvard Medical School, Boston, 1905; died May 2, aged 71.

Coit Inge Hughes, Phoenix, Ariz.; University of Louisville (Ky.) Medical Department, 1909; also a graduate in pharmacy; formerly secretary and superintendent of public health of Arizona; served during World War I, as county health officer and as a member of the state board of medical examiners; died May 4, aged 65.

Nicholas John Jackson, Joliet, Ill.; Jenner Medical College, Chicago, 1910; died May 7, aged 77, of carcinoma of the rectum.

Walker Allen Johnson, Orange, N. J.; Howard University College of Medicine, Washington, D. C., 1912; served during World War I; died May 7, aged 67.

William F. Johnson, Sebastopol, Miss. (licensed in Mississippi in 1907); died May 6, aged 73, of cerebral hemorrhage.

William P. Kelly ⊕ Pittsfield, Mass.; Albany (N. Y.) Medical College, 1892; chairman of the school board; affiliated with St. Luke's Hospital, Hillcrest Hospital and House of Mercy; died April 25, aged 76, of heart disease.

Earl Warren Keyes, Cleveland; University of Wooster Medical Department, Cleveland, 1908; medical examiner for the Prudential Life Insurance Company; died May 9, aged 64.

Richard Glenn Kibbey, New Hartford, N. Y.; Syracuse University College of Medicine, 1907; member of the American Medical Association and the American Society of Anesthetists; on the staffs of the Marcy (N. Y.) Hospital, Masonic Soldiers and Sailors Memorial Hospital and St. Luke's Home and Hospital in Utica, where he died May 6, aged 64, of embolism.

Jerome J. Klein ⊕ St. Albans, N. Y.; Georgetown University School of Medicine, Washington, D. C., 1937; diplomate of the National Board of Medical Examiners; interned at Easton (Pa.) Hospital; died April 19, aged 34.

Charles Edward Klontz ⊕ Cherry Valley, Ill.; Northwestern University Medical School, Chicago, 1905; on the staff of St. Anthony Hospital in Rockford, where he died May 13, aged 67.

Kate Krieger, Cincinnati; Cincinnati College of Medicine and Surgery, 1898; also a pharmacist; died April 26, aged 84, of senility.

Jesse L. Lambert, Franklin, W. Va. (licensed in West Virginia in 1895); served as mayor of Franklin, health officer and on the county school board; died in the Rockingham Memorial Hospital in Harrisonburg, Va., May 14, aged 76, of diabetes mellitus.

Charles Henry Lamon, New Kensington, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1929; on the staff of the Citizens General Hospital, where he died May 3, aged 43, of pneumonia and heart disease.

Ezra Cornell Lawrence, Los Angeles; Drake University Medical Department, Des Moines, 1891; member of the American Medical Association; died May 3, aged 85.

Edward Burton Lehman, New Haven, Conn.; University of Tennessee College of Medicine, Memphis, 1928; member of the American Medical Association; died in the Grace Hospital March 30, aged 46.

James Buchan Littlejohn, Chicago; University of Glasgow Medical Faculty, Scotland, 1892; College of Medicine and Surgery, Chicago, 1905; died May 21, aged 78.

George David Lowry, Hooker, Okla.; College of Physicians and Surgeons, Keokuk, Iowa, 1888; died May 4, aged 84.

Ransom Wight Luce, Grand Rapids, Mich.; Detroit College of Medicine, 1906; died May 2, aged 66, of influenza followed by uremia.

George Roscoe Luton ⊕ Santa Barbara, Calif.; Medical Faculty of Trinity University, Toronto, 1904; police commissioner; on the staffs of St. Francis Hospital and the Cottage Hospital, where he died May 20, aged 66.

Harrison Lee McCrary, Royston, Ga.; University of Louisville (Ky.) Medical Department, 1890; member of the American Medical Association; consultant in medicine at Brown's Hospital; died April 22, aged 81, of prostatic hypertrophy and uremia.

James William McCurdy ⊕ Thomaston, Ga.; University of Georgia School of Medicine, Augusta, in 1935; interned at the Grady Hospital in Atlanta; served in the Pacific theater during World War II; died in the Macon Hospital, Macon, April 28, aged 36, of injuries received in an automobile accident.

James Samuel McFadin, Altus, Okla.; College of Physicians and Surgeons, Dallas, 1906; died March 31, aged 68.

William Jerome McHugh, Scranton, Pa.; St. Louis University School of Medicine, 1922; member of the American Medical Association; on the staff of the Ransom Mental Hospital in Ransom; died April 9, aged 52.

John Paxton McInnes, Toledo, Ohio; Northwestern Ohio Medical College, Toledo, 1890; died April 5, aged 84.

Hugh Gordon McKay ⊕ Old Town, Maine; Tufts College Medical School, Boston, 1917; died April 28, aged 56.

William Monroe McKay, Salt Lake City; Rush Medical College, Chicago, 1925; member of the American Medical Association; secretary and state health commissioner and formerly director of the division of communicable disease, Utah State Board of Health; affiliated with the Thomas D. Dee Memorial Hospital in Ogden; died April 13, aged 59, of acute nephritis.

Herman Herve Mai, Chicago; College of Physicians and Surgeons of Chicago, 1890; member of the American Medical Association; died April 9, aged 81.

Robert George Mayer, Kaukauna, Wis.; University of Wisconsin Medical School, Madison, 1941; member of the American Medical Association; interned at the City Hospital in Cleveland; served in the medical corps, Army of the United States, in the Pacific theater during World War II and among other citations received the Bronze Star and the meritorious service award; affiliated with the Veterans Administration Hospital in Wood, where he died April 1, aged 32.

John Francis Messemer ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1915; on the staff of the Fordham Hospital; died April 16, aged 57, of pneumonia.

Leander Burgess Milbourne, Baltimore; University of Maryland School of Medicine, Baltimore, 1898; lieutenant commander in the U. S. Naval Reserve, serving in the Pacific theater during World War II; served during World War I; surgeon aboard the S. S. *Santa Isabel*, on which he died while at sea near Panama April 16, aged 67.

William Carlton Miller, College Springs, Iowa; Chicago Homeopathic Medical College, 1891; died April 25, aged 84, of carcinoma of the stomach.

Edwin Morrill Minnick ⊕ Danvers, Ill.; Rush Medical College, Chicago, 1895; an Affiliate Fellow of the American Medical Association; died in St. Joseph Hospital, Bloomington, May 2, aged 77, of cerebral hemorrhage.

William Moitrier, Brooklyn; Long Island College Hospital, Brooklyn, 1881; member of the American Medical Association; formerly on the staff of St. Catherine's Hospital; died in Brentwood, N. Y., April 20, aged 90, of cerebral hemorrhage.

Alice Tucker Moore, Denver; Gross Medical College, Denver, 1897; died April 24, aged 84.

Baxter Edward Morrow, Kansas City, Mo.; Beaumont Hospital Medical College, St. Louis, 1892; died April 27, aged 76.

Albert Thomas Murphy, Elizabeth, N. J.; Jefferson Medical College of Philadelphia, 1915; member of the American Medical Association; served during World War I; on the staffs of the St. Elizabeth Hospital and the Alexian Brothers Hospital, where he died May 16, aged 56, of coronary thrombosis.

Charles F. Murphy, Cynthiana, Ind.; Louisville (Ky.) Medical College, 1894; died in the Welborn Baptist Memorial Hospital in Evansville April 23, aged 74, of cerebral hemorrhage.

Frank A. Murphy ⊕ Philadelphia; Jefferson Medical College of Philadelphia, 1903; affiliated with the Misericordia and St. Mary's hospitals in Philadelphia and the Fitzgerald-Mercy Hospital in Darby, Pa.; died in Margate City, N. J., April 25, aged 65, of cerebral hemorrhage and hypertension.

Harry Spencer Noble, Lima, Ohio; Kentucky School of Medicine, Louisville, 1893; member of the American Medical Association; fellow of the American College of Surgeons; president of the Home Banking Company of St. Mary's and chairman of the board of directors; served overseas during World War I; member of the staffs of the Memorial and St. Rita's hospitals; died in St. Mary's May 6, aged 75, of coronary embolism.

William James Norton, Columbus, Ind.; Tennessee Medical College, Knoxville, 1894; member of the American Medical Association; formerly member of the city board of health; served during World War I; died in the Bartholomew County Hospital April 25, aged 82, of myocardial degeneration.

William Frederick Neumann, New York; College of Physicians and Surgeons, medical department of Columbia College, New York, 1892; member of the American Medical Association; died May 18, aged 75.

Henry Sidney Oaks, Rutledge, Tenn.; Lincoln Memorial University Medical Department, Knoxville, 1912; died April 7, aged 63, of cerebral hemorrhage and hypertension.

Albert Grove Odell ⊕ Clifton Springs, N. Y.; Syracuse University College of Medicine, 1904; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychiatric Association and the American Association for Mental Deficiency; for many years on the staff of the Clifton Springs Sanatorium and Clinic, where he died May 19, aged 68, of fibrosis of the lungs and cardiac failure.

Francis James O'Hara, North Adams, Mass.; Georgetown University School of Medicine, Washington, D. C., 1904; member of the American Medical Association; served as mayor of North Adams, member of the school committee, board of health and planning board; on the staff of the North Adams Hospital; died May 2, aged 68, of heart disease.

Alfred Gustav Pfeiffer, Paramus, N. J.; University of the City of New York Medical Department, New York, 1885; member of the American Medical Association and the Medical Society of the State of New York; served as president of the Police Pension Fund of Paramus; died April 28, aged 90, of hypertension and arteriosclerosis.

Paul West Winder ⊕ Shreveport, La.; University of Michigan Medical School, Ann Arbor, 1931; specialist certified by the American Board of Obstetrics and Gynecology; served during World War II; chief of the obstetric and gynecologic section, Highland Sanitarium; on the staff of the Charity Hospital; died May 5, aged 42.

fellow of the American College of Surgeons; member of the founders group of the American Board of Surgery; member of the American Association for the Study of Goiter; president of the park board; member of the advisory board and executive staff at St. Joseph Hospital; surgeon for the Childrens Dispensary and Hospital Association; chief of the surgical staff, member of the board of directors, advisory board and executive staff, Memorial Hospital, where he died May 11, aged 61, of coronary occlusion.

James Linn Adams, Van Nuys, Calif.; Missouri Medical College, St. Louis, 1886; died March 18, aged 87.

Sanford Bailey ⊕ Garden City, Kan.; Kentucky School of Medicine, Louisville, 1893; on the staff of St. Catherine's Hospital, where he died April 28, aged 75, of carcinoma of the pancreas.

William Dewey Balfour, Wailuku, Hawaii; Washington University School of Medicine, St. Louis, 1927; member of the American Medical Association; formerly vice president of the Territorial Association of Plantation Physicians; captain, National Guard, not on active duty; died April 13, aged 48.

Rose Anne Bebb ⊕ New York; University of Minnesota College of Medicine and Surgery, Minneapolis, 1897; affiliated with the Bellevue Hospital; died April 16.

Plumb Brown, Springfield, Mass.; the Hahnemann Medical College and Hospital, Chicago, 1892; died April 28, aged 78, of carcinoma of the intestine with metastasis.

Edwin Bunnell, Willows, Calif.; Medical Department of the University of California, San Francisco, 1894; died in the Woodland (Calif.) Clinic Hospital April 26, aged 77, of carcinoma of the right lung.

John Rollo Burr, South Bend, Ind.; Chicago Homeopathic Medical College, 1897; died in the Memorial Hospital April 4, aged 73, of cerebral hemorrhage and sarcoma of the rectum.

Russell Williams Chidsey, New Holland, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1890; served during the Spanish-American War; found dead April 25, aged 78.

Frances Cohen ⊕ New York; Cornell University Medical College, New York, 1900; formerly assistant director of educational hygiene for the city board of education and pediatrician in the department of health; served in the pediatric division of the Mount Sinai Hospital; died April 18, aged 73.

Ovee John Colwick, Durant, Okla.; Southwestern University Medical College, Dallas, Texas, 1906; member of the American Medical Association; died April 2, aged 66, of heart disease.

Max Davis, Boston; Harvard Medical School, Boston, 1925; diplomate of the National Board of Medical Examiners; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; fellow of the American College of Surgeons; assistant professor of gynecology and obstetrics at the Boston University School of Medicine; on the staffs of the Massachusetts Memorial and Beth Israel hospitals; died in Cambridge April 30, aged 46, of rheumatic heart disease.

Charles A. Dawson, Minden, Texas; Louisville (Ky.) Medical College, 1891; member of the American Medical Association; affiliated with the Henderson Memorial Hospital in Henderson; died April 26, aged 79, of diabetes mellitus.

Pasquale De Feo, Medford, Mass. (licensed in Massachusetts in 1905); died April 19, aged 72, of uremia.

Dell S. Edwards, Covington, Ky.; Woman's Medical College of Cincinnati, 1895; died April 24, aged 90, of heart disease.

Carl Hernfrid Fornell ⊕ New York; Harvard Medical School, Boston, 1914; specialist certified by the American Board of Otolaryngology; served during World War I; formerly medical director of the Hartford Accident and Indemnity Company; on the staff of the Manhattan Eye, Ear, Nose and Throat Hospital; died May 7, aged 60.

Joseph Foster ⊕ Santa Fe, N. M.; Western Pennsylvania Medical College, Pittsburgh, 1901; died April 21, aged 73, of carcinoma.

Charles Frederick Frankman, Greenville, Ohio; University of Michigan Medical School, Ann Arbor, 1928; affiliated with the Wayne Hospital; died April 25, aged 43, when struck by a train.

Maude Granger Furniss, Brookline, Mass.; Boston University School of Medicine, 1897; died April 14, aged 73, of chronic myocarditis.

Malcolm Brown Fyfe, Valparaiso, Ind.; Northwestern University Medical School, Chicago, 1903; member of the American Medical Association; served overseas during World War I; school physician at Valparaiso University; member of the city board of health; on the staff of the Porter Memorial Hospital; died May 11, aged 71, of rupture of an abdominal aneurysm.

Frederick Arthur Grossman, Wilmette, Ill.; Northwestern University Medical College, Chicago, 1897; served in the Coast Guard during World War I; died in the Illinois Central Hospital, Chicago, May 16, aged 76, of a hip fracture received in a fall.

William Hipp, Detroit; Detroit College of Medicine, 1906; member of the American Medical Association; died May 2, aged 69.

Arnold James Gelarie ⊕ Ossining, N. Y.; Thüringische Landesuniversität Medizinische Fakultät, Jena, Thuringia, Germany, 1910; member of the American Public Health Association and the American Association for the Advancement of Science and others; at one time bacteriologist with the public health service at the U. S. Quarantine Station, Port of New York; died May 7, aged 61.

Earl Ray Gibbs ⊕ Wilkinson, Ind.; Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1907; served during World War I; died in the Methodist Hospital, Indianapolis, May 13, aged 66, of carcinoma of the breast with metastases to the lung.

Jacob Benjamin Ginsburg, Boston; College of Physicians and Surgeons, Boston, 1920; died April 30, aged 65, of coronary occlusion.

Duke Marvin Godbey, Perryville, Ky.; Hospital College of Medicine, Louisville, 1905; member of the American Medical Association; died May 5, aged 68, of cerebral hemorrhage.

Orren Pakenham Goodwin, Ruston, La.; born in Longstaw, La., Nov. 18, 1881; Baylor University College of Medicine, Dallas, 1913; formerly affiliated with the Indian Service; served overseas during World War I; lieutenant colonel, medical reserve corps, not on active duty; served on the staffs of Veterans Administration hospitals in various places; formerly on the staffs of the State Hospital in Pineville and State Hospital in Little Rock; died in the Veterans Administration Hospital in Alexandria, April 26, aged 65, of heart disease.

John Monroe Gray, Joplin, Mo.; St. Louis College of Physicians and Surgeons, 1899; member of the American Medical Association; Spanish-American War veteran; on the staffs of St. John's and Freeman hospitals; died May 2, aged 73, of chronic myocarditis.

Angelina G. Hamilton, Anna, Ill.; the Hahnemann Medical College and Hospital, Chicago, 1897; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1908; affiliated with the Anna State Hospital; died in Port Huron, Mich., April 30, aged 74, of coronary thrombosis.

John E. Hetherington ⊕ Grand Forks, N. D.; Jefferson Medical College of Philadelphia, 1909; served as a member of the state medical board; on the staff of the Deaconess Hospital; died May 9, aged 62, of arteriosclerosis and cardiac failure.

Frank Wheeler Hornbrook, Chevy Chase, Md.; Harvard Medical School, Boston, 1905; died May 2, aged 71.

Coit Inge Hughes, Phoenix, Ariz.; University of Louisville (Ky.) Medical Department, 1909; also a graduate in pharmacy; formerly secretary and superintendent of public health of Arizona; served during World War I, as county health officer and as a member of the state board of medical examiners; died May 4, aged 65.

Nicholas John Jackson, Joliet, Ill.; Jenner Medical College, Chicago, 1910; died May 7, aged 77, of carcinoma of the rectum.

Walker Allen Johnson, Orange, N. J.; Howard University College of Medicine, Washington, D. C., 1912; served during World War I; died May 7, aged 67.

William F. Johnson, Sebastopol, Miss. (licensed in Mississippi in 1907); died May 6, aged 73, of cerebral hemorrhage.

William P. Kelly ⊕ Pittsfield, Mass.; Albany (N. Y.) Medical College, 1892; chairman of the school board; affiliated with St. Luke's Hospital, Hillcrest Hospital and House of Mercy; died April 25, aged 76, of heart disease.

Earl Warren Keyes, Cleveland; University of Wooster Medical Department, Cleveland, 1908; medical examiner for the Prudential Life Insurance Company; died May 9, aged 64.

Richard Glenn Kibbey, New Hartford, N. Y.; Syracuse University College of Medicine, 1907; member of the American Medical Association and the American Society of Anesthetists; on the staffs of the Marcy (N. Y.) Hospital, Masonic Soldiers and Sailors Memorial Hospital and St. Luke's Home and Hospital in Utica, where he died May 6, aged 64, of embolism.

The Norwegian Pharmacopeia

The latest edition of the Norwegian pharmacopeia was published in 1913! To be sure, a new edition was in preparation in 1939, but it got no further during the war, and now its publication in its 1939 form is being discussed with some misgiving. In this form it was not much more up to date than the Danish pharmacopeia of 1933. Meanwhile Denmark possesses an official pharmacopeia which has recently been brought up to date. Why not, it is argued, ignore the 1939 draft of the Norwegian pharmacopeia and boldly adopt the Danish pharmacopeia as Norway's own, pending the issue of a really up to date Norwegian pharmacopeia? Would this mean loss of prestige for Norway? Quite possibly. But would that matter much in comparison with the advantages to be gained? Already the Scandinavian countries have pooled their medical activities in some textbooks and in the conglomerate weekly journal *Nordisk medicin*.

A National Campaign Against Cancer

Norway ought long ago to have had an influential body representative of modern medical science to lead the campaign against cancer. We have, to be sure, an organization known as the Norwegian Association for Combating Cancer. Its most influential and active member is a layman, lawyer Eckbo, who to his own satisfaction has traced cancer to a faulty diet. In his advocacy of this theory in his recent book on cancer he has quoted the writings of the Norwegian pathologist Professor Kreyberg. The professor's protest that he had been misquoted has led to legal proceedings ending in a fine for Eckbo and the suppression of his book. In the light of this incident the time seems ripe for the creation of a representative national organization against cancer unhampered by a reputation for eccentricity. But how much easier it is to start with a clean slate than one blurred by erasures!

A Study of Gastroduodenal Ulcer

During the war years 1941-1944 a Norwegian surgeon working in the far north of Norway devoted much of his time to an intensive study of the conditions under which gastric and duodenal ulcer developed in a population mainly concerned with fishing. With the aid of the Dr. Malthe Foundation, this surgeon, Dr. Kaare Schanke, has succeeded in publishing his study as a supplement to *Acta chirurgica Scandinavica*. One of the most remarkable of his observations was that in a group of islands to the north of the polar circle, gastric ulcer was far more common than duodenal ulcer, a reversal of the relationship of the two to each other in most other regions. Gastric ulcer was more frequent in the rural than in the urban districts, whereas the opposite was the case with duodenal ulcer. Dr. Schanke found that irregularities in the mode of living of fishermen were the most important causes of gastric ulcer, and he is inclined to suspect that one group of causes is responsible for most cases of gastric ulcer, and another group for most cases of duodenal ulcer.

Paul Owren and His Parahemophilia

We are all proud of Paul Owren on account of his recent contribution to hematology. He was born in 1905 and, after graduating at Oslo University in 1931, settled down to private medical practice, the drudgery of which he enlivened by fox farming. His artificial insemination of foxes was pioneer work which helped to render this hobby quite lucrative. Throwing off the shackles of a general practitioner in 1938, and financed by his foxes, he returned to the wards of the Rikshospital in Oslo, where he encountered a remarkable instance of hemorrhagic diathesis which had lasted since childhood in a woman aged 29. In a tiny laboratory equipped with a more or less home-made outfit, he came to the conclusion that the greatly reduced coagulability of this patient's blood was due to the absence of a hitherto unknown clotting factor which is necessary for normal clotting and which he has called factor V. He has found the differential diagnosis between hemophilia and what he calls parahemophilia easy, as the faulty coagulation of the latter is not returned to normal by the addition of thrombokinase, as in the case of hemophilia. In his opinion parahemophilia is probably not hereditary.

Experimental Study of Brazilian Blastomycosis

Progress in knowledge of the infection produced by Paracoccidioides brasiliensis has been gained by an experimental study by Drs. Francisco Fialho and A. Padilha Gonçalves recently published. Following the way opened by J. Montenegro, whose studies have been previously reported, Fialho and Gonçalves observed the evolution of experimental lesions produced by intratesticular inoculations of guinea pigs. The authors disclosed an early reaction of the reticuloendothelial system, observed simultaneously with a leukocytic infiltration within twenty-four hours of the inoculation. This first reaction progresses to an exudative phase with formation of abscesses, and later to another, productive, with granulomatous organization. At a given time there is a balance between the exudative and the productive processes; after this the exudative changes become predominant, and gradually larger abscesses are formed. However, the productive process, which appears as early as the exudative one, is observed until the end. Although a longer period of observation would be desirable, the evolutionary progression of the lesions observed by Fialho and Padilha was logical and satisfactory. The presence of the fungus in its yeastlike form on the sixth day of infection led the authors to suggest the use of the inoculation of animals for diagnostic purposes, by injecting several guinea pigs, some of which should be killed in the course of the first month. By this procedure it is possible to confirm the diagnosis earlier. Once more the authors succeeded in observing the minute types of Paracoccidioides brasiliensis and the possibility of this fungus reproducing itself in the tissues by single budding, in addition to its characteristic reproduction by cryptosporulation. The authors believe that these conclusions must be submitted to further confirmation and other complementary studies which they are now performing.

Etiologic Frequency of Heart Diseases

Dr. Jairo Ramos, professor of medicine at the Paulista Medical School, has published a paper in the series of cardiologic studies he is undertaking. The paper concerns the etiologic frequency of heart diseases in general hospital patients. In a total of 1,700 adult patients, Ramos disclosed 457 cases of heart disease, thus demonstrating the high incidence (26.3 per cent) of these diseases in hospital patients. According to the etiology, the cases may be classified as rheumatism 110 (24.0 per cent), syphilis 83 (18.2 per cent), other infections 2 (0.4 per cent), nonrenal hypertension 59 (12.9 per cent), renal hypertension 49 (10.8 per cent), pulmonary hypertension 25 (5.5 per cent), sclerosis 79 (17.3 per cent), thyrotoxicosis 5 (1.1 per cent), neurocirculatory asthenia 8 (1.7 per cent), congenital malformations 2 (0.4 per cent), traumatism and tumors 3 (0.7 per cent) and other causes and unknown 32 (7.0 per cent).

The cases in which rheumatism was the etiologic factor include 89 with valvular lesions (80.9 per cent) and 21 with nonvalvular lesions (19.0 per cent). The valvular lesions were mitral stenosis and insufficiency 47 cases (52.8 per cent), pure aortic insufficiency 16 cases (17.9 per cent), aortic insufficiency and mitral stenosis 19 cases (21.2 per cent), aortic stenosis and insufficiency 3 cases (3.3 per cent), mitral stenosis and aortic stenosis and insufficiency 2 cases (2.2 per cent), mitral and aortic stenosis 1 case (1.1 per cent) and aortic stenosis 1 case (1.1 per cent). The 21 cases of nonvalvular lesions include 20 of chronic myocarditis and 1 of acute myocarditis associated with acute dry pericarditis. The 108 cases in which arterial hypertension was the etiologic factor include benign hypertension 48 cases (44.4 per cent), malignant hypertension 8 cases (7.4 per cent) and hypertension from acquired stenosis of the abdominal aorta, nodose periarteritis and paroxystic hypertonia 1 case each (0.9 per cent), acute glomerulonephritis 28 cases (25.9 per cent) and chronic glomerulonephritis 21 cases (19.4 per cent). The third important etiologic factor was syphilis, with 83 cases thus distributed: aortic insufficiency 60 cases (72.2 per cent), aneurysms 19 cases (22.8 per cent), and simple aortitis 4 cases (4.8 per cent). The 79 cases in which sclerosis was the etiologic factor included 69 cases of myocardiosclerosis (87.3 per cent), 2 cases of aneurysm (2.6 per cent) and 8 cases of aortic insufficiency (10.1 per cent).

NAPLES, June 19, 1947.

Anniversary of Forlanini's Discovery

Precisely a hundred years ago, in 1847, the inventor of artificial pneumothorax, Carlo Forlanini, was born in Milan. Italy is preparing fitting honors for him on the occasion of the celebration of the anniversary of his discovery. The pneumothorax of Forlanini is still practiced throughout the world, though ideas have been somewhat modified since its original application. Forlanini considered the lung to be a wounded organ, incapable of healing, owing to the continual movement undergone during respiration. And so it was necessary to cause it to relax, retaining it at the same time in its full anatomic form by introducing aid intrapleurally. According to Forlanini, in other words, a diseased lung, for recovery, had to be rendered "static and full." This concept is now changed, as it is known that not only in the lung but in other organs too, for example the kidney, existing tuberculosis sometimes becomes even more grave under such conditions.

Anterolateral Thoracoplasty

However, the great benefits reported by the applications of Forlanini's method of intrapleural pneumothorax led investigators to continue research based on this principle. Pneumothorax treatment was unsatisfactory when diffuse adhesions existed between the two pleural layers and when the lesions of the lung involved large cavities and extensive destruction. So followed thoracoplasty in which successive ribs are cut away and the wall of the thorax collapses rigidly and firmly over the diseased lung (in a way, a surgical application producing a "static" lung of Forlanini's original concept), which becomes transformed into a relaxed organ, still retaining its form. It was found, however, that a lung treated in this way did not quite heal from tuberculous lesions: the remaining healthy tissue of the lung was damaged and often aggravated the situation. Following Sauerbruch's thoracoplasty came partial thoracoplasty in which the "demolishing" effect of the sudden collapse of the thorax over the lung was avoided: but even this was not free from criticism. It was then that Monaldi, graduate of the school of Forlanini and later noted in America and elsewhere for his method of "suction drainage," proposed what is known as anterolateral thoracoplasty. Here the aim of the surgeon is not a large reduction in lung space but to modify the tractive force of the thorax, reducing the forces exerted on the lung during normal respiration. That is, to relax the lung but to leave it still capable of performing its respiratory functions, particularly in the nonaffected parts. These adjust themselves to the conditions so as to compensate for the losses in the affected areas of the lung.

Further advances were made mainly through the work of Smith and Omodei-Zorini, present head of Italy's largest sanatorium in Rome, and another of Forlanini's school, in the development of extrapleural pneumothorax: in this, air is introduced at the back of the parietal layer. It is in many cases more effective than Forlanini's intrapleural procedure, but not so "demolishing" as the thoracoplasty of Sauerbruch and Graff.

Monaldi's Suction Drainage

Then followed the now popularly established method of Monaldi's suction drainage. In this a long, narrow catheter is introduced into the cavity of the affected lung and is connected to a suction apparatus by means of which the cavity can be drained. At first this procedure provoked criticism and was treated with reserve, though now its acceptance is world wide. There is no doubt that extraction of toxic matter from the infected parts produces beneficial results, in aiding the self-healing tendencies of the tissues and in cleaning out the lung. Maier spoke of Monaldi's method in 1944 during his talk to the medical section at the fortieth annual meeting of the National Tuberculosis Association in Chicago. He said that the Monaldi procedure "may result in apparent closure of the cavity with the conversion of the sputum, but even after subsequent thoracoplasty performed to maintain closure, the cavity may reopen to large size. As far as I know, the literature does not contain any large series of cases in which intracavitary suction drainage was followed by thoracoplasty and final results were evaluated." However, following the increasingly large number of favorable results of the Monaldi system (also in America), any doubts which Maier had must have subsequently been dispelled. In the *Journal of Thoracic Surgery* (**15**:153 [June] 1946) J. R. Head refers to 29 cases treated with Monaldi's suction method at the Edward Sanatorium, with analysis of the results obtained. The treatment may be applied alone, but often it is aided by thoracic surgery. Sometimes an operation on the phrenic nerve is performed for immobilization of the diaphragm. Immobilization of the hemilateral diaphragm relaxes the lung, and extraction from the cavity can then be carried out more fully and completely. At other times Monaldi's suction is associated with thoracoplasty.

Recently an important congress of tuberculosis surgeons in Italy, presided over by Monaldi himself, was held. The leading specialists in the country were present. Many reports were read, and supported with statistical evidence, and the results of various forms of treatment were given. Monaldi described fully the various methods: thoracoplasty, extrapleural pneumothorax and Monaldi's suction, applied either alone or in conjunction with other procedure.

Suction Drainage with Streptomycin

Head, in the article quoted, states that "Monaldi's method has come to occupy an important place in the treatment of pulmonary tuberculosis." There is every reason to believe that it will become even more important, especially in the light of modern antibiotic treatment. Modern treatment seeks for more direct, immediate introduction of the drug (as for example penicillin or streptomycin in disorders of the central nervous system, direct into the vertebral column) and to introduce streptomycin directly to the affected part of the lung. The method of Monaldi suggests the best means of doing this. The catheter can equally serve as a means of introducing the drug or cleaning out the cavity. Monaldi is probably already applying this method, at the moment, in the large sanatorium, which he personally directs. But reports of results have not yet been officially published

Correspondence

POLIOMYELITIS AND PREGNANCY

To the Editor:—There is a growing feeling among physicians in certain quarters that susceptibility to poliomyelitis is increased during pregnancy. The experience in Florida during the 1946 outbreak, in which 572 cases were reported, possibly may be of interest.

Eight cases occurred among pregnant women, all of whom were in the second and third trimester. In this group there were two deaths, one of which was the only case in a pregnant Negro woman. Of the 6 remaining patients, 1 was in a respirator for a long time. Five women resided in Key West, which had a total of 45 cases with an attack rate of 2 per thousand. Four of the women in Key West were wives of navy personnel. Investigation in that city revealed no specific factors to explain the large number of pregnant women affected.

On the other hand, there were 78 cases of poliomyelitis among women of both colors in the age group 15 to 44, which might be considered the child bearing age. This would give a rate of 14 cases per hundred thousand for this group. During 1946 there were slightly over 55,000 births, from which a rate of 14 per hundred thousand for pregnant women can be computed. It would seem that, based on this small number of cases, there is no difference in the susceptibility between pregnant and nonpregnant females in the child bearing age.

Edwin G. Riley, M.D., Jacksonville, Fla.
Epidemiologist, Florida State Board of Health.

LEPROSY

To the Editor:—The following are my observations on the comments of Dr. G. W. McCoy of New Orleans (The Journal, Dec. 14, 1946, p. 947):

1. That early lesions of leprosy may be confused with the sarcoids, lupus erythematosus and syphilis, see pages 269-272 of McCarthy's Histology of Skin Diseases (St. Louis, C. V. Mosby Company, 1931), and note the following: Figure 115 from Kyrle's histopathology; "Boeck and Mazzi found acid-fast bacilli in nasal secretion"; figure 116 and description of histology of angiolupoid. They are indistinguishable from bacterionegative or the paucibacillated form of tuberculoid leprosy in reaction. I agree with the use of laboratory tests including histology, but, besides their limitations, how many dermatologists make use of them, how many patients are examined neurologically (Wise, Fred, in discussion, The Journal, Oct. 23, 1943, p. 470), and how many are followed up for years to await the possible appearance of Mycobacterium leprae? (Velasco: *Internat. J. Leprosy* 9:91, 1941). Kyrle's instructive case of lupoid cited by McCarthy (p. 271) is no different in behavior bacteriologically and histologically from reacting tuberculoid leprosy. Rabello (The Journal, Aug. 15, 1935, p. 1205) contends that all symptoms of Besnier-Boeck's disease may be caused by leprosy, as proved bacteriologically, histologically and by animal inoculation. These diseases produce chronic inflammatory granuloma, and I do not know of any differential characteristics (see again Wise, p. 471).

2. Pathogenically, early leprosy lesions on contact children appear and progress for years without demonstrable bacilli by numerous and periodic examinations. Therefore the pathologic changes produced must be due to a "virus." Carreon (Transaction Open Meeting, Leprosy Advisory Board, p. 69, Bureau of Printing, Manila, 1932) examined twelve families of 12 segregated children and found either father or mother M. leprae negative clinical or suspected lepers; in no case were both parents with lesions; besides the parents, 9 other children were found clinical or suspected lepers. Velasco (Revista Filipina de Medicina y Farmacia, **25**:423, 1934) examined 15 bacteria negative clinically leprous parents and 46 of their children; he found 8 bacillated and 27 clinical lepers among them; in thirteen families both parents were examined, and in twelve only one spouse had the disease; in the thirteenth family both spouses had leprosy, but they came from the same endemic town and both have relatives as inmates in Culion Leper Colony. Adult immunity and infectiousness of the microscopically negative are evident.

3. As to "persons unquestionably infected during adult life," how exclude individuals as the Molokai cases under observation for a number of years by McCoy (Pub. Health Bull. 66, Washington, 1914) and finally confirmed but "which clinically gave only trifling evidences of skin lesions and none whatever that would under ordinary circumstances have been regarded as suspicious of leprosy," becoming manifest lepers after a history of contact in adult life? Nothing less than experiment is required to prove adult susceptibility. But since lesions may spontaneously but temporarily disappear according to observations on contact children, even one or several negative skin and neurologic examinations before the experiment cannot exclude existence of a latent infection.

4. I agree that Philippine control measures would be unnecessary in the United States, but the reason is not experience but infant protection, because even through education alone, leprosy infection in Texas and Louisiana can be prevented or reduced. This happened in Balala, Culion and Minnesota, where only the male Scandinavian lepers (Gronvold: *J. Cutan. & Ven. Dis.*, 1884, No. 2, p. 17) raised families with nonleprous wives; direct contact was mostly or entirely with the mothers, only indirect with the leprous fathers.

5. Proof of infantile susceptibility and adult immunity is based on an overlooked fundamental that under natural conditions transmission (or nontransmission) of a thoroughly understood communicable disease (bacterial, parasitic or insect borne) obeys a certain universal and obligatory biologic law. This is independent of those governing individual, local or regional clinical variations, and time required for their appearance. Forty years of observation in Culion Leper Colony shows that in Balala, the nonleprous district, with a population of about 1,000 employees, laborers including their families, only 2 adults developed manifest leprosy; the first had a leprous brother, the second a leprous first cousin as inmates in the colony. Daily direct contact of lepers with employees is the rule, and so is indirect contact with their children. Yet the disease failed to spread. This occurs in all similar leprosariums and explains clearly the disappearance of the disease among the descendants of Minnesota male lepers. Barring historical evidences which are subjective and therefore unscientific in leprosy study, adult immunity is a universally established fact not only by experience, but epidemiologically and by recorded experimental inoculations of man. In the leper district adjoining Balala, Lara (*Monthly Bull., Bureau of Health* **22,** 1946) found that at least 50 per cent of contact children of lepers showed at one time or another before the age of 5 years unequivocal leprosy lesions, some of which disappeared entirely. Since the biologic law governing nontransmission of leprosy (adult immunity) in Balala, Culion, is universal and obligatory, therefore the law governing transmission (infantile susceptibility) observed in the leper district of Culion must indubitably be identical with that controlling transmission elsewhere.

[A correction: In the fourth paragraph, fifth line, of my communication in The Journal, Oct. 19, 1946, page 407, "allowing the child" should read "allowing the patient to pursue a normal productive life."]

MEDICOLEGAL ABSTRACTS

Right of Court to Order Physical Examination of Plaintiff in Personal Injury Case.—The plaintiff sued the defendant druggists for injuries alleged to have resulted from the faulty filling of a prescription From a judgment dismissing the cause, the plaintiff appealed to the Supreme Court of Idaho.

The trial of this case was set for a Monday morning On the preceding Monday the plaintiff's counsel was requested to have the plaintiff submit to a physical examination by the defendant's physicians The plaintiff's counsel was then acquiescent but he advised the defendant on the following Thursday that the plaintiff would not submit to an examination by one of the physicians selected Other physicians were then suggested, but plaintiff's attorney advised defendant that plaintiff would not submit to a physical examination by any doctor other than her attending physician On Saturday the defendant secured a court order requiring the plaintiff to submit to a physical examination at 12:30 on that day at the office of one of the selected physicians Telephone conversations ensued between plaintiff and one of the physicians, the court and plaintiff's attorney, and plaintiff then indicated a willingness to submit to the examination but later stated she could not be present and secure attendance of her physician at that time 12:30 went by and, after further negotiations, the meeting was deferred to 1:30. Plaintiff then stated that the time was too short, that she was engaged in taking care of a child and an older person and could not be present. As a result, no physical examination was made on Saturday. On the Monday morning set for a hearing the defendant moved, on affidavits pro and con, to dismiss the case because of the plaintiff's failure to comply with the court order. At this hearing the plaintiff testified that she had told her attorney "before 12:00 Saturday, that you (she) would submit to that (physical) examination at 4:00 o'clock that afternoon." At the conclusion of the hearing, in plaintiff's presence in open court, plaintiff's attorney stated "At this time we renew our offer to submit to an examination." Whereupon defendant's counsel renewed his objection to the offer and the trial court dismissed the cause. The record indicates that the plaintiff had no objection to the two physicians last suggested by the defendant to conduct the examination if her physician could also be present, which was agreeable to all On appeal the plaintiff argued that the trial court abused its discretion in dismissing the suit and that the trial court had no authority to enter an order requiring plaintiff to submit to a physical examination.

The Supreme Court reviewed all the cases in both state and federal jurisdictions which have considered the question and concluded that a majority of the decisions recognize the discretionary power of a court to order an examination by physicians suggested by the defense and approved by the court, and to enforce noncompliance of such an order by dismissal In this case, however, said the Supreme Court, the time fixed by the trial court for the examination was too short and the dismissal was unjustified because, while plaintiff perhaps unnecessarily delayed the examination on Saturday, she had a right to arrange to have her physician present at a time reasonably convenient to her. In ordering the examination a court should give due regard to plaintiff's health, and the time and place, though imperative and requiring prompt and immediate compliance therewith, should be reasonable as to all parties, permitting plaintiff to have present such attendants, reasonably limited as to number, as she may desire.

Accordingly the Supreme Court reversed the judgment of dismissal and remanded the cause to the trial court for further proceedings.—*Greenhow v. Whitehead's, Inc., 175 P. (2d) 1007 (Idaho, 1946).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Endocardiac Electrocardiogram.—Battro and Bidoggia of Buenos Aires studied the electrocardiographic variations in 23 persons as registered by endocardiac catheterization. The tracings show mainly the variations of potential of the heart, detected at the endocardiac surface The auricular endocardiac electrogram (endocardiac P wave) consists normally of a series of rapid deflections (S, e, i, o waves) joined to a final slow deflection (Ta wave) by means of the o-u segment. The shape of the auricular electroendogram undergoes modifications according to the position of the electrode inside the auricle. Rapid deflections represent the process of depolarization of the auricles Repolarization is represented by the final slow portion, as in the ventricular complex. The initial negative deflection (S wave) of the auricular complex is regarded as an exponent of the activity of the sinoauricular node. The endocardiac ventricular electrogram undergoes modifications in shape, depending on whether the electrode is placed in the right ventricle or right auricle. The authors describe the electroendogram obtained from the ventricle (type I) and from inside the auricle (type II). They also describe the variations of endocardiac potential in bundle branch block, in 1 case of auricular extrasystoles, in 1 case of auricular asynchronism and in cases of premature contractions of the right and left ventricles The electrocardiographic curves registered with the catheter placed in the superior and inferior venae cavae and at different sites in the venous system are described In the cases of bundle branch block the endocardiac electrogram shows the same characteristics that have been observed in experimental bundle branch block in the dog

Myocardial Depression in Shock.—Wiggers and his associates studied the hemodynamics of hemorrhage and shock with the hope of elucidating especially the cardiovascular mechanisms involved in irreversibility. The cardiodynamic changes which occur after simple hemorrhage, during prolonged hypotension, during reinfusion of all the withdrawn blood and during spontaneous circulatory failure following infusion were studied in the same animal. Following simple hemorrhage sufficient to reduce mean arterial pressure to 50 mm. of mercury, the changes in ventricular actions are all secondary to reduction in venous return and decrease in effective central venous pressure. Electrocardiograms do not reveal significant changes. Changes in the contour of the central arterial pulse consist in abridgment of the period of systolic ejection and development of a primary spike followed by a peaked summit, and this is followed by a deep incisura. As a result of decreased venous pressure, ventricular filling is slower, initial tensions decrease in both ventricles, and their diastolic size is smaller. Pressure and volume curves indicate that the ventricles expel their diminished volumes with good velocity. If severe posthemorrhagic hypotension is prolonged for 135 minutes, death results from an oligemic type of failure unless blood is reinfused. Such reinfusion is of only temporary benefit; circulatory failure and eventually death follow. Irreversibility develops during the period of prolonged hypotension. This includes depression of the myocardium. Reinfusion of blood restores arterial pressures and pulses as well as cardiac output to normal, but in order to do so the ventricles are required to operate under supernormal conditions of high venous pressure and initial tensions. As soon as these reestablish at normal levels, cardiac output decreases and the ventricles pump less efficiently, owing to a depressed state of the myocardium. As arterial pressure declines, reduction in venous return becomes so great that the myocardial depression is obscured, though it is detectable by special tests. A progressive circulatory failure develops despite the fact that blood volumes are not significantly decreased. This represents a form of normovolemic shock due solely to default of the peripheral circulation and of the myocardium. Since the functional state of the myocardium and the capacity of the coronary responses at the time of shock-producing catastrophes may often be below par, myocardial depression may play as significant a subsidiary role in some cases of human shock as it did in animals submitted to a particular type of hemorrhage and shock.

Effective Dose of Oral Penicillin Preparations.—Hoffman and Volini assayed the plasma penicillin levels achievable with varying doses of penicillin administered orally and with a large variety of preparations, with and without diluents, antiacid substances or buffers. Doses of 25,000 units were usually ineffective in producing appreciable plasma penicillin levels. When 50,000 units was administered every two hours, plasma levels of 0 06 unit per cubic centimeter were frequently achieved.

but there were too many zero levels and too few levels higher than 0.06 unit per cubic centimeter to make the dosage a reliable substitute for parenteral therapy. Doses of 100,000 units, when preceded by a primary dose of 200,000 units one hour earlier, gave levels averaging higher than 0.125 unit per cubic centimeter for the first two hours and about 0.06 unit for the next two hours. Such levels were comparable to those obtained with intramuscular injections of 20,000 units every three hours. At this dosage there were no great differences in the results with the various preparations. Doses of 200,000 units gave perceptible plasma levels even at six and eight hours after the dose. From these observations, the therapeutic regimen established was a primary dose of 200,000 units followed by 100,000 units every three hours.

Oral Penicillin in Pneumococcic Lobar Pneumonia and Other Acute Infections.—Hoffman and Volini treated 49 patients who had pneumococcic lobar pneumonia and 81 patients who had miscellaneous infections produced by penicillin-sensitive organisms by administering orally several preparations of penicillin in primary doses of 200,000 units followed by 100,000 units every three hours. In 37 patients with pneumonia, fever and toxic symptoms subsided within forty-eight hours and in some patients within twelve hours. Of the remaining 12 patients failure was due to (*a*) inadequate absorption of penicillin, (*b*) the presence of penicillin-insensitive organisms such as a virus, (*c*) penicillin-resistant pneumococci or (*d*) overwhelming complications. The patients with miscellaneous infections responded similarly well to oral management with penicillin, those with hemolytic streptococci rapidly and those with staphylococci more slowly. The results were comparable to the authors' experience with parenterally administered penicillin. The plasma penicillin levels under this regimen were usually 0.06 unit per cubic centimeter or higher during most of the three hour interval between doses. Urticaria occurred in 5 (3.8 per cent) of the 130 treated patients. When purified preparations were used, only 2 spurious cases of urticaria developed. The severity of the infection has been found to have no relation to the penicillin dosage required. Only the sensitivity of the organism to penicillin should be the determining factor in dosage.

Penicillin in Early Syphilis.—Clark and his co-workers studied the serologic response following penicillin therapy in 208 patients with previously untreated primary or secondary syphilis. The serologic response observed during the first eight weeks following penicillin therapy for early syphilis is comparable to that previously reported during weekly treatment with the several arsenical drugs. Since some of the latter agents are known to be therapeutically inferior, this observation reemphasizes the fact that, *in the final evaluation of antisyphilitic drugs*, serologic response is not an all important criterion of therapeutic efficacy. In a comparison of the serologic response during the first eight weeks following penicillin with that previously recorded during weekly arsenical treatment by stage of disease (seropositive primary, early secondary and late secondary syphilis), an apparent retardation in the rate of fall of serum reagin following penicillin was observed. The serologic trends recorded during the first year following penicillin therapy provide evidence of a linear relationship between duration of infection and rate of fall of serum reagin—the longer the duration of disease the slower the serologic response. Studies of the effects of age, race and sex on the serologic response showed a delayed rate of fall of serum reagin in Negro females and in the youngest age group under 20 years. Evidence is presented that the retarded response observed is related (in these groups) to a higher percentage of patients who had (*a*) longer duration of disease, (*b*) the least efficacious treatment scheme or (*c*) a high incidence of subsequent relapse, or to a combination of these factors.

Monoplegia in the Aged.—Zeman and Siegel report 1 case of irreversible cerebral damage following carotid sinus pressure. A man aged 83 with long-standing hypertension developed a permanent right monoplegia within a few minutes after routine testing of carotid sinus responsiveness. The test should be reserved for cases in which it will serve a diagnostic or therapeutic purpose of definite importance. It should not be used as a routine test in patients past 50 and it should not be employed in the elderly to stop attacks of supraventricular tachycardia except in the unusual and obstinate cases when other measures have failed.

Dust Control and Disinfection of Air.—According to Loosli the bacterial content of dust found in homes, schools, factories, offices and hospitals varies with the different environments. Saprophytic organisms usually predominate, but parasitic and pathogenic agents may be found in large numbers. There are ample data to show that dust is an important vehicle for the spread of certain diseases of bacterial and virus etiology in the laboratory, hospital wards and army barracks. It most likely plays an equally important role in the spread of infections in schools and homes. Ultraviolet light, glycol vapors and hypochlorous acid employed in the disinfection of air have only a limited effectiveness against dried dust borne organisms. Oiling floors, bedclothes and other textiles is a highly effective procedure for the control of dust, lint and dust borne bacteria. The action of the oil is a mechanical one only. Although the most important "environmental reservoirs" of pathogens found in hospital wards are the floors and bedclothes, all surfaces, as well as all textiles (blankets, sheets, pajamas, clothes of attending nurses and doctors) should be oiled to bring about the maximum dust control. Studies indicate that oiling floors, bedclothes and other textiles can effect a significant reduction in the incidence of respiratory tract infections of streptococcus etiology in hospital wards and army barracks.

Examination for Tuberculosis in Army.—Long and Hamilton say that as of Aug. 1, 1945 approximately 15,065,000 Selective Service registrants in the 18 through 37 year age groups had been physically examined at local boards and induction stations, of whom 4,828,000 had been placed in class 4-F. Of this number 129,900 were so classified because of tuberculosis. This represents 2.7 per cent of all men in the 4-F class and 8.6 men per thousand examined. The rejection rate for tuberculosis in selectees dropped from 14.9 per thousand in 1942 to 7.8 in 1945. The rate was continuously higher for white persons than for Negroes. Some liberalization in application of standards for acceptance, and a lowering in age of selectees, were the chief apparent reasons for the decrease. The curve of hospital admission rate for tuberculosis in the army was characterized by high points at the beginning and end of the war. The peak at the beginning was due to inadequacy of induction examination, with resultant acceptance of numerous men found later to be tuberculous. The high point at the end was due to discovery of cases in the course of physical examination on discharge. Discharge for tuberculosis totaled approximately 15,000 men in the years 1942-1945 inclusive. About 60 per cent of the patients admitted to hospitals for tuberculosis were ultimately discharged as having active tuberculosis. In physical examination on separation a large number of cases of minimal tuberculosis were discovered. The rate of discovery was higher in men with oversea service than in men without, a fact suggesting that new infections were acquired in greater number overseas than at home.

Q Fever at National Institute of Health.—Huebner says that between Dec. 17 and May 30, 1945 an outbreak of Q fever involving 47 persons occurred in a single building of the National Institute of Health, Bethesda, Md. The outbreak was unique in three respects: (1) the large number of human cases involved (47), (2) the apparent variation in immunologic status of the several populations at risk and (3) a concomitant outbreak in two guinea pig colonies in the same building. Clinical as well as serologic evidence of Q fever was detected in 44 of 142 workers and in 3 of 55 visitors to this building. Rocky Mountain spotted fever tick vaccine and exposure during a previous outbreak of Q fever were factors possibly tending to reduce the incidence of Q fever during the 1946 outbreak. A chronologic study of cases in laboratory workers showed a correlation between the dates of preparation of yolk sac antigens and the probable dates of exposure in the cases. The unsuspected resistance of Rickettsia burneti to such chemical agents as solution of formaldehyde and the manipulations required in preparing antigens were considered to be possible factors in the outbreak. Guinea pig excreta were also considered a possible source of the human outbreak, since viable R. burneti have been recovered from the urine of guinea pigs months after defervescence of the disease.

Pneumoperitoneum.—Mitchell and his co-workers employed artificial pneumoperitoneum in the treatment of 710 patients with pulmonary tuberculosis. Four hundred and seventy-four of these patients were so treated for three months or longer. The report is based on this group except for the complications which cover the entire 710 cases. The use of pneumoperitoneum for an average of 54.5 weeks was responsible for 57 per cent satisfactory results in 188 white patients and, used for an average of 50.5 weeks, was responsible for 37 per cent satisfactory results in 286 Negro patients with advanced pulmonary tuberculosis not amenable to conventional forms of collapse therapy. Pneumoperitoneum was useful in relieving symptoms in terminal tuberculosis and it was occasionally useful in obliterating old pneumothorax spaces in which the lung had failed to reexpand, in obliterating empyema spaces and in controlling pulmonary hemorrhage when other methods failed. An abdominal binder is a useful adjunct to pneumoperitoneum in most patients. The complications of pneumoperitoneum given to 710 patients for periods ranging from one dose to 306 weeks were minor in 8.6 per cent and major in 4.7 per cent; pneumoperitoneum was the direct cause of death in 1 case. Pneumoperitoneum was responsible for a significant increase in the failure of diaphragms to regain normal function following phrenic crush. Tuberculous enteritis is a contraindication to the method. The possibility of using pneumoperitoneum should always be considered in planning the treatment of advanced pulmonary tuberculosis.

Pulmonary Function Following Pneumothorax.—Birath studied 25 patients with pleurisy with effusion without parenchymal lesion and in whom so-called preventive pneumothorax treatment was terminated by his method of estimation of the total lung volume and its subdivisions and of the respiratory dead space. Total and vital capacities were diminished. Equilibrium and residual capacities were not generally diminished to the same degree, and their share in the total capacity was thus increased. While the diminished total and vital capacities were due to the impairment of the thoracic and diaphragmatic mobility through pleural adhesions, the cause of the increased relative lung volume values was a hypoventilation of certain parts of the lung, provoked by the same cause. In an additional 11 cases with completed pneumothorax treatment and with more or less extensive parenchymal lesions, the majority presented low total and vital capacities, considerable increase of the relative lung volume values and in certain cases increased values for the respiratory dead space. The cause of the serious impairment of the lung function was in some cases in part parenchymal contraction with so-called compensatory emphysema and reduction of the parenchyma, but in the majority of cases the cause was pleural changes following pneumothorax treatment (ventilatory insufficiency). It is suggested that in certain cases, when a lung retraction complicates pneumothorax treatment, the treatment should be abandoned and replaced with other collapse measures.

Chemotherapy of Tuberculosis.—Smith and his co-workers studied the chemotherapeutic efficacy of (1) the sodium salt of 4-amino-4'-galacturonylaminodiphenylsulfone (galacturonide), (2) 4-amino-4'-ureidodiphenylsulfone (carbamyl), (3) 4-amino-4'-n-propylaminodiphenylsulfone (n-propyl) in experimental tuberculosis of guinea pigs in comparison with sodium p,p'-diaminodiphenylsulfone-N,N'-didextrosesulfonate (promin). The chemotherapeutic effectiveness of these compounds, expressed as the ratio between the extent of tuberculous involvement in the controls and treated animals, was 2.7 for compound 1, 2.6 for compound 2 and 2.8 for compound 3 as compared with 2.6 for promin. The n-propyl derivative is less than one fifth as toxic as promin. The chemotherapeutic effectiveness in a group of animals treated with streptomycin and compound 1 was 27.0. Seventy-five per cent of the animals in this group showed no gross evidence of tuberculosis or only doubtful and insignificant lesions, though 95 per cent of them reacted to intracutaneous tuberculin, and subinoculation tests with tissue suspensions gave positive results in nearly all cases. The combined application of streptomycin and the monogalacturonyl derivative of 4,4'diaminodiphenylsulfone in the treatment of experimental tuberculosis gave as good results as those previously reported with streptomycin and promin.

Asymmetry in Occipital Electroencephalograms.—Sugar undertook a study of asymmetry in side-to-side distribution of electrical activity in the human brain, because of the occurrence of differences in routine clinical electroencephalography. Over 1,000 patients were examined by means of a four channel electroencephalograph, using the standardized army technic for electrode placement, time of recording and basic interpretation. In migraine, neurocirculatory collapse, cephalalgia, intracranial masses and intracerebral disease such as hemiplegia and hemianopsia, asymmetries appeared in numbers which are statistically significant as compared to normals. No such significant results were obtained with epileptic, psychoneurotic or psychopathic personalities, in posttraumatic syndromes and infections of the nervous system or in persons with syncope. Twenty per cent of the patients had depression of the alpha activity of the left occiput, 8.2 per cent had depression of the right occiput, and 71.8 per cent had equal amounts of alpha activity on the two sides. The corresponding figures for amplitudes were 14.1, 8.1 and 77.8 per cent. In the absence of gross cerebral abnormalities, such depressions of amplitude and alpha activity may be due to diminished blood supply to the affected side. The presence of such asymmetries is considered to be an aid in the diagnosis of migraine and other disorders of cerebral circulation.

Histamine Antagonists.—Rose and his co-workers determined the protective effect of antihistaminic drugs by injection of histamine in the dorsal vein of the penis of the guinea pig fifteen minutes after the animal had received the protecting drug intraperitoneally. Anaphylactic experiments were carried out by intracardiac injections of horse serum forty eight hours after intraperitoneal administration of pooled rabbit anti-horse serum. Protection against anaphylaxis was afforded by methods similar to those used against histamine. Studies parallel to those conducted in anaphylaxis in the intact animal were carried out on the sensitized intestinal strip of the guinea pig. The protection afforded against anaphylactic shock by the antihistaminic drugs studied (benadryl, pyribenzamine, antergan and neoantergan) decreases as the amount of the drug is decreased. All the compounds studied showed essentially similar protection against anaphylaxis. Observations on the sensitized intestinal strip of the guinea pig bear out the lack of difference of protection rendered by benadryl and neoantergan in anaphylaxis in the intact animal. Against a single lethal dose of histamine the antihistaminic drugs studied are almost equally effective. Observations on the sensitized intestinal strip indicate that the anaphylactic contraction was inhibited by an amount of antihistaminic drug which had no effect on the contraction of the same magnitude due to histamine.

Contact Type Eczematous Dermatitis.—According to Sulzberger, allergic contact type eczematous dermatitis is to be considered as an entity which is (1) by definition "allergic," (2) which is usually produced by contact of the sensitized skin cells with the allergen coming from without and (3) which is a dermatitis that presents the clinical and histopathologic picture characteristic of eczematous changes. Both prognosis and therapy of this dermatitis are different from those of seborrheic dermatitis, nummular eczema, atopic dermatitis or many forms of dermatitis due to direct damage by chemical and physical agents. Prevention and treatment must be confined to the discovery and elimination or reduction of contact with the causal allergen and, in addition, to the appropriate forms of local dermatologic management.

Toxic Reactions of Atabrine Dihydrochloride.—Reviewing observations made on air force personnel, Smith says that the administration of atabrine dihydrochloride in certain doses is associated with a high incidence of gastrointestinal disturbances. The suppressive doses associated with the highest toxicity were those in which 0.2 Gm or more was given as a single dose twice a week on nonconsecutive days. Toxic reactions were infrequent with daily doses of 0.1 Gm.

Penicillin in Osseous Congenital Syphilis.—Hill and his associates show that osseous congenital syphilis is a dynamic process which waxes and wanes as the infant grows older. Control data were derived from 134 roentgenographic observations on 98 infants before penicillin therapy was started. Inspection of the curve for total severity of untreated lesions shows that 1 to 90 days of age represents the period of increasing severity, 91 to 210 days that of rapidly decreasing severity, 211 to 365 days that of moderate decline, and 13 to 24 months that of slow decline. Improvement results from decreasing severity of osteomyelitis and osteochondritis, periosteal changes increase in prominence over a longer period and persist as the commonest residuums. The course of a given lesion cannot be accurately predicted. Dosages of penicillin employed so far have temporarily accelerated healing of osseous syphilis only in infants treated during the first three months of life. This acceleration occurs principally in osteochondritis and osteomyelitis, simultaneous improvement in periostitis is only of probable significance. No such significant effects were observed among those treated during the next four months. The mode of healing for any particular type of lesion, as herein described, has not been evaluated. *Increase in severity of these lesions during* or shortly after penicillin therapy occurs in an age group in which this phenomenon is to be expected without treatment. Pseudoparalysis disappears without specific changes in the roentgenograms; indeed, osseous lesions may even appear worse after pseudoparalysis subsides.

Evaluation of Antihistaminic Drugs in Allergy.—Ratner arrives at the conclusion that the release of histamine has not yet been proved to be the fundamental factor in anaphylaxis or allergic reactions; hence any therapy based on such a concept must be called into question. Benadryl and pyribenzamine and other drugs of this group have not been proved to be antihistaminic, either chemically or pharmacologically. These drugs have not proved of value in the eradication of allergic syndromes. They do not appear to prevent the entrance of antigen into the circulation and the antigen-antibody reaction. It is the nature of the allergic episode to be self limited, and it is often spontaneously terminated. For this reason a wide variety of drugs seem to relieve it. Benadryl and pyribenzamine alleviate symptoms of diverse allergic conditions. The greatest benefits are derived in acute urticaria and hay fever in allaying pruritus and nasal and lacrimal discharges. These drugs should have a place along with epinephrine, ephedrine and atropine as excellent antispasmodics. They are not as efficient in asthma and eczema, the more chronic and fixed syndromes. These drugs must be used vigilantly because they may have serious side effects which may affect the higher brain centers. They deserve a place in our armamentarium as symptomatic remedies, but the author deplores that some physicians and particularly the lay public, as a result of widespread publicity, feel that they are cures.

Gelfoam Hemostasis in Prostatic Surgery.—According to MacDonald and Powell fibrin foam fulfilled all criteria of an ideal hemostatic agent for prostatic surgery, but more recently there has been produced a synthetic substance called gelfoam. It closely resembles fibrin foam in appearance, is used in exactly the same way and possesses all the desirable characteristics of the original substance. It is available for clinical use in the form of small wafers. The authors review observations on 15 cases, in 3 of which fibrin foam was used and in the other gelfoam. In 1 of these cases hemostasis was not satisfactory. In this case the bleeding was probably arterial in type. In all other cases almost complete hemostasis was achieved. No clots formed in any case, the drainage fluid was never more than pale pink and within forty-eight to seventy-two hours it became perfectly clear. The authors think that with the use of either gelfoam or fibrin foam the mortality rate of prostatic surgery should be considerably reduced, since shock due to excessive bleeding has always been an important cause of its mortality.

Brucellosis in the United States.—According to Schmidt, the majority of the cases of brucellosis in the United States are of the abortus variety. In consideration of the widespread prevalence of the organism in milk and dairy products, it is not surprising that the abortus variety should attain a more rapid and greater attenuation than would the suis or melitensis types. The true incidence of the disease is not known, but the widespread distribution of the organism in milk and the attenuation of it by the cow over many years has resulted in a chronic and obscure disease most difficult to diagnose and obstinate to treat. The attenuation of Brucella abortus has detracted much from the value of laboratory procedures for diagnosis.

Effect of Ultraviolet Air Sterilization in Children's Institution.—Installation of ultraviolet radiant units in the children's building of St. Luke's Convalescent Hospital subjects every cubic foot of air in the building to a sterilizing effect equivalent to more than 100 complete air changes per hour. The output of the bulbs is tested periodically with a Luckiesh-Taylor ultraviolet meter containing a special fluorescent material whose maximum sensitivity is for 2,537 angstroms radiation. If the efficiency of the lamps falls below 75 per cent of their original output the incidence of infection begins to rise. Frequent dusting of the lamps is important. During 1943 the lights were turned off for several months because of a shortage of bulbs, and the incidence of infections showed an upward trend. During the three year control period 3.98 per cent of the children were febrile, as against 2.38 per cent for the three year experimental period. This shows a difference of 1.60 per cent, or eleven times the standard error of the difference. Comparison of the control and experimental periods during the winter months alone again shows a difference of 1.96 per cent, which is again eleven times the standard error of the difference. These figures indicate a reduction of 33 per cent in the number of children febrile from respiratory disease for the treated years as against the untreated years. House plants do not tolerate the ultraviolet radiation and usually die. Otherwise there have been no deleterious effects from the lights. The children have no difficulty in sleeping in the faint glow, which resembles moonlight. The attendant staff soon observed that the usual children's institution odor had completely disappeared, and some of the nurses commented on the freshness of the atmosphere.

Low Toxicity of Sulfonamide Mixtures.—Lehr studied the toxicity, the absorption and the excretion of the combinations sulfadiazine-sulfathiazole, sulfadiazine-sulfamerazine and sulfadiazine-sulfathiazole-sulfamerazine in albino rats. These combinations of partial dosages proved significantly less toxic than any one of their separate constituents in equal or comparable total dosage. The mixture of three sulfonamides was less toxic than either combination of two drugs. Mixtures of sulfonamides were more completely absorbed and excreted than equal amounts of their individual constituents. Blood levels from mixtures were distinctly higher than expected on the basis of mathematical computations from the values of single sulfonamides. It was reasoned that the use of a mixture containing three sulfonamides in human therapy would almost completely eliminate the possibility of concrement formation in the urinary tract at the routine dose level.

Reaction of Human Body Louse to Ingestion of Guinea Pig Blood.—Experiments reported by Cabasso indicate that, contrary to general belief, guinea pig blood per se is not toxic to the human body louse. Although experiments proved that the red blood cells of guinea pigs remain undigested in the intestine of the louse, additional experiments proved that lice fed once on guinea pig blood live their normal life span when their daily feedings are continued subsequently on human blood.

Mass Infection of Lice with Rickettsia Prowazeki.—Cabasso demonstrates that human body lice fed once on a typhus infected guinea pig at the height of the febrile period, and subsequently fed on a typhus immune human being, develop massive infection with Rickettsia prowazeki. In comparison with the rectal inoculation of lice for the preparation of the Weigl type typhus vaccine, this method of infecting lice seems to offer certain advantages.

Cross Reactions Between Histoplasmin and Blastomycin.—Howell says that the specificity of the histoplasmin reaction in man has become of great importance since the demonstration of a high degree of correlation between pulmonary calcification and sensitivity to histoplasmin in individuals who do not react to tuberculin. Three lots of histoplasmin and five of blastomycin and heat-killed antigens prepared from yeast cultures of Histoplasma capsulatum and Blastomyces dermatitidis have been tested on guinea pigs experimentally infected with Histoplasma capsulatum and Blastomyces dermatitidis. It has been shown that the number of experimentally infected guinea pigs which reacted to histoplasmin, blastomycin or the heat-killed yeast phase antigens depends on the particular lot of antigen and its dilution. If the critical titers of these antigens are determined and if these concentrations are used to study cross reactions, the degree of cross reaction between these antigens is small and the antigens are therefore relatively specific for guinea pigs experimentally infected with the homologous fungi. It is necessary to consider the degree of sensitivity of the animals employed to determine the titer of an antigen, that is, if the sensitivity level is low, a high concentration of the antigen will have to be used to elicit a reaction, and therefore a false impression of the critical titer of the antigen will be obtained. Such high concentrations of antigen will produce a high percentage of cross reactions.

Use of Succinylsulfathiazole and Phthalylsulfathiazole in Surgery of Colon.—Poth shows that evidence has been accumulating over the past five years which indicates that succinylsulfathiazole and phthalylsulfathiazole, when properly administered, are bacteriostatic agents which will modify the bacterial flora of the bowel contents, allow a satisfactory preoperative mechanical preparation of the colon, favor early healing of the colon at the line of suture and reduce the incidence of postoperative peritonitis and wound infection. The judicious use of these drugs during the preoperative and postoperative surgical periods decreases the operative mortality following colonic surgery and simplifies the surgical procedures. The proper use of succinylsulfathiazole and phthalysulfathiazole requires that they be used as adjuvants to and not as substitutes for established surgical practices.

Translumbar Aortography in Management of Hydronephrotic Kidney.—Doss points out that poor concentration of radiographic mediums or the apparent delay in excretion of a substance used in determining renal function no more justifies the removal of an enlarged hydronephrotic kidney than does a reasonably normal retrograde pyelographic shadow in an unobstructed poorly functioning kidney necessarily demand its preservation. When employing various solutions and mediums in an attempt to determine the true worth of the kidney, too much attention has been paid to the anatomic appearance of the kidney, at the same time giving too little attention to the effect the dilution factor of accumulated urine within the pelvis has on the mediums employed to estimate function. Actually, the enlarged and seemingly worthless kidney may be a better unit functionally and therefore more capable of sustaining life than the other more normal looking one. It has been the author's practice to obtain an arteriogram before renal exploration Pursuing the policy that a kidney is no better than its arterial supply he has chosen, when surgery seemed indicated, to spare no effort to preserve the hydronephrotic kidney presenting a good blood supply. He thinks that we should be far more conservative about removing hydronephrotic kidneys, particularly in the younger age group, than has been the custom.

Neuroanatomic Report on Prefrontal Leukotomy.—In a paper published in 1945 Meyer and his associates dealt with the therapeutic and psychiatric aspects arising out of prefrontal leukotomy. In the present review they deal exclusively with neuroanatomic investigations carried out on patients dying at various intervals after prefrontal leukotomy. The report is concerned with 7 leukotomized and 1 lobectomized human hemispheres.

Disease of Nervous System Occurring Among Workers Investigating Swayback in Lambs.—According to Campbell and his associates swayback is a paralytic disease of newborn and young lambs which occurred in many parts of Britain. The symptoms consist of ataxia and paralysis, the lambs either walking with a staggering gait or being completely paralyzed and unable to rise. The pathology is a symmetrical cerebral demyelination and degeneration of the motor tracts. Four of 7 persons who worked intensively on the demyelinating disease known as swayback in lambs developed a disease of the central nervous system clinically indistinguishable from disseminated sclerosis. This might be due to a heretofore unidentified occupational hazard of chemical research workers or it might also indicate that there is some causal connection between swayback and disseminated sclerosis, and some consideration has been given to speculation along these lines, viz. to some common infective agent acting only in the presence of a trace element deficiency. As swayback is a demyelinating disease and can be prevented by copper therapy, it is apparent that trace element deficiencies should be considered in connection with analogous diseases of man.

De Morgan's Spots.—According to Murison and his associates the minute round ruby colored macules known as De Morgan's spots are of common occurrence in adults. They are most often seen in the skin of the abdominal wall. They vary in size up to a diameter of about 5 mm. and in number up to twenty or occasionally more. Microscopically they have the character of simple hemangiomas. The authors discuss a possible connection with cancer. In order to obtain more data on the incidence and significance of these spots they studied their occurrence in 1,300 patients at three Glasgow hospitals. No difference was found in sex incidence. The proportion of hospital patients with ruby spots rises from 5 per cent in adolescence to about 75 per cent at 70 years of age. The spots also increased in number and size with advancing age, but their rate of growth decreased. De Morgan's spots were slightly commoner in malignant than in nonmalignant disease but not sufficiently so to be of diagnostic importance.

Postmortem Aspects of Tropical Eosinophilia.—Viswanathan says that since there have been no deaths from tropical eosinophilia the pathologic aspects of the condition have been a matter of speculation. He made postmortem studies on a man aged 28 who died of arsenical encephalopathy after the second injection of neoarsphenamine. The microscopic appearances in this case were suggestive of an infective process rather than an anaphylactic reaction. The lesions are peribronchial and not perivascular. The microscopic changes suggest that infection in tropical eosinophilia is probably by inhalation and that the infecting agent gets into the peribronchial tissue and sets up an inflammatory process involving the interstitial tissue mainly and alveoli partially. Discrete scattered areas of cellular infiltration, monocytic and eosinophilic, are produced. When the process becomes chronic, nodules containing giant cells and monocytes are formed. The disseminated mottled shadows seen in the x-ray films of cases of tropical eosinophilia and which last only for a short period are probably due to the areas of cellular infiltration with monocytes and eosinophils. In some cases the mottling lasts for months. In them the shadows might be due to the presence of giant cell nodules.

Writer's Cramp.—Narasimha says that writer's cramp, graphospasm or mogigraphia may be defined as a condition of incoordination of the small muscles of the hand which appears only when one attempts to write. The various names given to this condition emphasize that cramp or spasm is the predominant feature. As the principal nerves and muscles are often intact and movements of a wider range can be carried out efficiently, the condition appears to be a functional disturbance of coordination. Among the etiologic factors, overwork and excessive use of the hand for writing have been stressed. Janet includes the condition among the symptoms of "psychasthenia." Strümpell pointed out that this condition was often associated with a nervous constitution and that neurasthenic symptoms were often present *in persons suffering from writer's cramp.* The author found that 171 out of 1,880 (or approximately 1 in 11) patients suffering from neuropsychiatric conditions showed some incoordination of the muscles of the hand resulting in writing disturbances. Those in whom the *tremulous form* of writing was found had acute and severe anxiety neurosis. Those in whom the spastic or cramped form of writing was found, as well as those who showed the ataxic or jerky form of writing, had neurosis with hysterical reactions. Those who showed the paralytic form of disturbance, characterized by slovenly and almost illegible writing, were suffering from organic disease of the central nervous system. The term "writing disturbance" has been suggested instead of the name "writer's cramp."

Antithyroid Activity of Ergothioneine.—Lawson and Rimington point out that the discovery of the goitrogenic action of thiourea has led to an investigation of the activity of many types of thiol compounds. Thiouracil and its more active propyl derivative have been proved valuable in the treatment of hyperthyroidism, but these drugs have the disadvantage of producing toxic symptoms such as agranulocytosis. Since all the symptoms heretofore tested have been products foreign to the animal body, it was felt that ergothioneine, a *normal constituent of* blood, which belongs to the same chemical type, would be worthy of investigation. Ergothioneine is methyl betain of 2-thiolhistidine. The ergothioneine used in this work was isolated from ergot of rye. It was *observed that when ergothioneine* was administered subcutaneously to rats it exerts an antithyroid activity comparable with that of thiouracil. The possibility of using ergothioneine as a therapeutic agent which might be less likely than the synthetic compounds to produce toxic symptoms comes to mind, and this aspect of the problem is receiving attention.

Meperidine Hydrochloride (Demerol) Addiction.—Polonio says that in 1944 he and Barahona collected 17 cases of meperidine addiction from the literature with 3 deaths and presented 6 cases of their own with 1 death. Since then he has observed 9 more cases of meperidine addiction with 1 death. He stresses that the *therapeutic use of meperidine can be the source of* dangerous addiction and that it should be used with the same precautions as are required with morphine. Special care must be observed with certain personalities of the psychopathic type. *Tolerance and physical dependence are easily acquired.* Symptoms of intoxication are frequent and severe and may be cause of death. In 32 reported cases there were 5 deaths. Though the physical dependence and abstinence symptoms are not so intense as with morphine, the quicker habituation and more serious intoxication effects may well make meperidine a more dangerous drug.

Streptomycin in Experimental Plague.—Herbert says that streptomycin has given good results in the treatment of tularemia. *Streptomycin inhibits* the growth of the plague bacillus in vitro and in certain concentrations brings about rapid sterilization of plague cultures. In mice infected subcutaneously *with a highly virulent plague strain,* in dosage sufficient to kill 100 per cent of control animals, two and one-half day courses of streptomycin injections (800 units a day) at once and twenty-four and forty-eight hours after infection gave 85, 60 and 5 per cent survival. A dosage of 1,600 units a day for three and one-half days gave better results. In guinea pigs infected by subcutaneous injection, three and one-half day courses of streptomycin injections (40,000 units per kilogram daily) gave *100 per cent survival,* even when dosage was delayed for forty-eight hours after infection. Streptomycin is equally *effective in the treatment of artificially induced pneumonic plague* in both mice and guinea pigs. Penicillin and sulfathiazole also inhibit *the growth of Pasteurella pestis,* which in vitro appears more sensitive than most gram negative organisms to these drugs. In comparative tests in infected mice, however, streptomycin was considerably more effective than sulfathiazole, and penicillin was only slightly effective even in very high dosage.

***Hypopituitarism, Hypogonadism and Anemia Treated* with Testosterone.**—Watkinson and his associates point out that the pituitary plays a part in hemopoiesis, polycythemia being associated with basophilism, and anemia with hypopituitarism. The 2 cases of hypopituitarism and hypogonadism described here are unusual in that the associated anemia was resistant to treatment with liver, thyroid or iron but responded dramatically to injections of testosterone propionate. These 2 patients were men of 20 and 52. In the belief that testosterone might benefit other refractory anemias it was administered to 2 other patients whose anemia had proved resistant to treatment but in whom no evidence of pituitary or gonadal deficiency was present. The drug failed in these patients to have any persistent beneficial effect, confirming that it would be effective only in the presence of gonadal deficiency. The drug induced a temporary remission in 1 case, suggesting that it is worth a trial in refractory anemias, especially if associated with a hypocellular marrow. The evidence produced shows that hypogonadism may be important in the production of anemia, and testosterone may have *a good effect in cases of this type.*

Reflex of Rossolimo.—According to Rimbaud and his co-workers the first description of the reflex under consideration was given in 1902 by Rossolimo, who designated it as a "deep reflex of the great toe" which is elicited by percussion of the plantar surface of the great toe in the presence of a lesion of the pyramidal bundle. Later the study of the reflex was extended to other toes. Rimbaud and his co-workers studied the reflex in various forms of hemiplegia and emphasize that it is a deep reflex resulting from an interoceptive excitation. As such it differs from cutaneous reflexes resulting from exteroceptive stimulation as does the Babinski sign. The authors conclude that Rossolimo's toe flexion reflex is obtained by plantar percussion of the intrametatarsophalangeal space. It is a latent tendinous reflex which appears in the course of a lesion of the pyramidal tract, particularly in its medullary course. It is a sign of the onset of multiple sclerosis appearing before Babinski's sign, and it may be the only manifestation of a pyramidal lesion.

*Value of Determination of Hemoconcentration with Regard to Diagnosis, Prognosis and Therapeutic Indications in Shock During War. P. Royer and J. Barbizet.—p. 609.

Distribution of Rh Group in France.—Tzanck and Bessis studied fifteen erythroblastic families and found that 14 of the 15 mothers had Rh-negative blood and the one woman who was Rh positive was of the Rh_2 type and had an agglutinin anti-Rh_2 in her serum. The husbands of these women and their children had Rh-positive blood. Eleven of the 15 mothers of newborn infants with hemolytic disease had anti-Rh agglutinins in their serum; 7 of them had a standard anti-Rh agglutinin (delta); 1 had an anti-Rh_2 (H) agglutinin and 1 had a standard anti-Rh agglutinin in incomplete form (delta^1) and 2 had a mixture of anti-Rh and anti-Rh_1 (gamma + delta) agglutinins. This study demonstrated that statistics of Rh groups among the French white population are similar to those of the white population in England and in the United States. So far only two of the five types of antiserum discovered in the latter countries proved usable in the fifteen families studied. The other three types of antiserum are rare.

Hemoconcentration in Shock.—Royer and Barbizet failed to demonstrate hemoconcentration either on single or on repeated hematologic examination of 28 wounded soldiers with shock. These soldiers had sustained wounds of the abdomen, thorax, extremities, face and neck. There was no relationship between the intensity of the shock and the concentration of the red blood corpuscles. In 3 of the wounded a concentration of red blood corpuscles slightly above the normal and a relatively increased arterial tension were in contrast to the clinical symptoms of definite shock and the fact that these soldiers had suffered severe loss of blood. They very likely presented a posthemorrhagic reflex polyglobulism associated with contraction of the spleen. Hemoconcentration is an insufficient aid to diagnosis of shock and may even lead to an erroneous diagnosis because of the fact that wound shock differs definitely from histamine shock. Systematic studies of hemoconcentration in shock may be omitted, while pulse and arterial tension determinations are decisive in estimating the required amount of fluids. The choice between plasma and blood is to be based on the nature of the wound, on the importance of the hemorrhage and on the actual availability of blood and plasma.

Relation Between Cell Structure and Carbohydrate Metabolism. O. Riesser.—p. 131.

Traumatic Thrombosis of Splenic Vein.—Geiser and Studer say that although the symptomatology of thrombosis of the splenic vein shows considerable uniformity, there are numerous etiologic factors, among which trauma is infrequent. In the case under consideration a fall from a ladder on the left side was the traumatic cause. Diagnosis proved difficult because of the absence of esophageal varices. The epinephrine reaction, the leukothrombopenia, the history of the trauma and the formation of a collateral circulation in the left side of the abdomen facilitated a correct diagnosis. Differentiation from thrombosis of the portal vein was not definite. Since clinical symptoms had persisted from the time of the trauma to the roentgenologic demonstration of the splenic tumor, twenty-two days later, the trauma seemed established as the causal factor, although trauma is a rare cause of thrombosis of the splenic vein. Splenectomy is advisable in case of hemorrhages from esophageal varices or if the size of the splenic tumor causes complaints. However, if extensive varices develop in the splenic region of the abdominal wall, ligation of the splenic artery is to be preferred to splenectomy; this is the case also in the presence of extensive adhesions of the spleen.

*Myoma of Uterus and Arterial Blood Pressure. A. Wolff Neto, J. Hamermesz and N. A. Salum.—p. 75.

Uterine Myoma and Hypertension.—Observations on a group of white and a group of Negro women between the ages of 20 and 60 with myoma of the uterus (198 patients) and without uterine myoma (120 patients) revealed that hypertension and myomas of larger size were more frequent in Negro women than in white women. The incidence of hypertension in white women was the same for those with and without myoma, whereas in Negro women it was greater for those with myoma. Regardless of race, hypertension was more frequent and more intensified in women having myomas of large size than in those having myomas of medium or small size. Larger myomas were encountered in Negro women.

Excessive Reactibility to Sandfly Bites. S. Gill.—p. 104.
Pemphigus and Allied Conditions: A Review. M. Michael.—p. 106.

Quick Staining Method for Treponema Pallidum.—Since available Treponema pallidum stains are not suitable for the practitioner's office, Cohen describes the requirements of such a technic and outlines one which has advantages owing to the greater ease and rapidity with which it is performed and the greater reliability of results. The serum must be spread in a thin film, and fixation is done by covering the slide with a 36 to 40 per cent solution of formaldehyde with subsequent heating until evaporation is noted. The slide is then flushed with distilled water. For staining Cohen employs 4 drops of a solution consisting of equal parts of normal sodium hydroxide and tenth normal sodium hydroxide, 2 drops of a 5 per cent solution of iron chloride, 4 drops of normal hydroxylamine hydrochloride and 3 drops of a 10 per cent solution of pyrogallic acid. The slide is then heated until bubbles appear under gentle stirring. This is followed by flushing with distilled water, after which a few drops of an ammoniacal solution of silver nitrate in 0: 5-5 per cent solution are added. After a few seconds staining is complete. The slide is then washed with distilled water and air dried. Under the microscope the treponemes display a reddish brown color on a light background in artificial light. It is important that none of the solutions required need be freshly prepared. The entire process takes only one minute.

Ectodermosis Erosiva Pluriorificialis Due to Phenobarbital.—According to Berlin phenobarbital produces exanthems which are mostly morbilliform or scarlatiniform in about 3 to 4 per cent of patients. Another type of reaction is the severe variant of erythema multiforme accompanied with fever and involvement of the mucous membranes and generally known as ectodermosis erosiva pluriorificialis (Rendy-Fliesinger). In 1 of the 3 cases of ectodermosis erosiva pluriorificialis a patch test with a 20 per cent solution of the drug elicited a slightly positive reaction. In 2 cases the intracutaneous test with a solution of 2 per cent was strongly positive. The diminishing of the reaction after repeated and increased oral test doses in 1 case speaks for the possibility of a specific desensitization.

- Keratoconjunctivitis Sicca in Cases of Rheumatoid Arthritis. T. Stenstam.—p. 131.
- Studies of Infectious Mononucleosis. E. Klemola.—p. 149.

Familial Leukemia.—According to Videback observations of familial leukemia have grown so numerous that one cannot rule out factors of heredity as contributory causes of the disease. This theory receives support from the observation of leukemia in identical twins and the occurrence of leukemia in successive generations and in 3 or 4 members of the same family. The author was able to detect 11 instances of familial leukemia. The familial occurrence of leukemia was 7.6 per cent of all the cases, that is, it was as frequent as that of pernicious anemia. As regards the relative frequency of the different forms of leukemia, the familial cases show the same distribution as a nonselected material, and on an average familial leukemia manifests itself at an earlier age than leukemia in general. These circumstances indicate that familial leukemia is, at least partly, of hereditary origin, and that its occurrence depends on a common leukemic gene. The manner in which this gene is inherited is as yet unelucidated, but irregular dominance is most likely.

Calcinosis Universalis.—The patient with calcinosis universalis presented by Lebel and Randløv-Madsen was a girl aged 9. The disorder had lasted about four years. Severe contractures and huge lime salt deposits had developed around the large joints. An attempt was made to influence the lime salt deposits by means of an alkalizing treatment consisting in giving large quantities of sodium citrate by mouth. The treatment had no effect. The rarity of calcinosis universalis is indicated by the fact that only about 80 cases have been reported since 1877. It is most frequently observed in childhood and early adolescence.

Symptomatology and Prognosis of Lipoid Nephrosis.—In order to get an idea of the prognosis of lipoid nephrosis, Laake made follow-up studies on patients who had presented the picture of lipoid nephrosis while under hospital observation. At the time of hospitalization all of them had manifest edemas, and 7 were found to have hydrothorax and/or ascites. There also were found hypoproteinemia, inversion of the albumin/globulin ratio, hypercholesterolemia, hypocalcemia and normal xanthoprotein values. Thirteen of the 16 patients were investigated. Two of these had become free from symptoms after an illness lasting four months and one and one-half years. The length of the observation time for these patients was five and fifteen years, respectively. Both of them were 11 years old when the disease first appeared. Six of the patients reexamined still presented symptoms of the renal disease, 4 had died of chronic glomerulonephritis with uremia and 1 had died of cardiac infarction. Microscopic examination of the kidneys also revealed changes typical of chronic glomerulonephritis. The author concludes that adults who present the clinical picture of lipoid nephrosis really have a chronic glomerulonephritis, which in many cases has a more protracted and benign course than what is usually seen.

Curative Effect of Duodenal Juice of Swine in Pernicious Anemia.—Landboe-Christensen and Bohn were able to collect from a hog with a pouch and fistula arrangement large quantities of pure duodenal juice. They tested the possible efficiency of this secretion in pernicious anemia. Treatment with the duodenal juice was first tried on a man aged 83, with negative results. The authors obtained a curative effect in a previously untreated case of pernicious anemia; the patient was given ten daily doses of 150 cc. of pure duodenal juice. The bone marrow reacted in the typical way. Discrepancies between this observation and the experiments of Castle, Townsend and Heath may find an explanation in the fact that the duodenal secretions in man and in swine may differ regarding their anti-pernicious anemia effect, but a relationship between pernicious anemia in man and the duodenoprival anemia in swine seems to have been established.

Acute Anterior Poliomyelitis in Pregnancy.—Grelland describes the course of acute anterior poliomyelitis in pregnancy observed in Ullevål Hospital in 10 patients aged from 20 to 41. Of the 6 patients given respirator treatment the 4 in the last three months of pregnancy died. Four healthy children were born, in 1 instance by cesarean section. There was 1 abortion, and in 1 case the pregnancy is not yet terminated but the prognosis is favorable. Microscopic examination of mother and child in 2 instances showed extensive lesions in the spinal cord and medulla oblongata in the mothers, while the nervous system appeared to be normal in the fetuses. Of 58 cases of poliomyelitis in pregnancy reported in Scandinavian literature, including the 10 here reported, 29, with 1 death, occurred in the first six months of pregnancy and 29, with 14 deaths, in the last three months of pregnancy. The deaths were due to respiratory paralysis. In 4 cases the result of the pregnancy is not known. In 3 cases delivery was by cesarean section, in 32 it was spontaneous; 30 healthy children were born. Grave paralysis of the lower extremities and abdominal musculature does not affect the course of delivery. Respiratory paralysis in the last three months of pregnancy is considered an indication for immediate cesarean section.

Animal Experiments and Histologic Observations on Function of Parathyroids in Man.—Wilton concludes that hypercalcemia in hyperparathyroidism occurs because the hormone excess in some way leads to dedifferentiation of mature bone cells with consequent dissolution of precipitated calcium salts. Hyperparathyroidism in osteitis fibrosa generalisata seems in most cases to depend on an intermittent irritation of the parathyroid parenchyma. This irritation may possibly originate from the hypophysis.

Book Notices

Recent Progress in Hormone Research: Proceedings of the Laurentian Hormone Conference. Volume I. Edited by Gregory Pincus. Cloth. Price, $7.50. Pp. 399, with illustrations. Academic Press Inc., 125 E. 23d St., New York 10, 1947.

The Laurentian Hormone Conference, the successor to the Gibson Island Hormone Conference, has established a reputation for scientific excellence although only three annual meetings have been held. Sharply restricted in its membership, the proceedings of this conference have not been available to those not fortunate enough to be invited to participate, except through widely scattered publications in which part of the material given at one of the conferences is presented.

Under the able editorship of Dr. Pincus, the entire proceedings, including discussions, of the 1946 conference have been gathered together. The papers, although dealing with highly specialized topics in hormone chemistry and physiology, should, by the excellence of presentation and their authoritative authorship, find wide acceptance among all scientists interested in endocrinology.

The proceedings are divided into four parts, the first dealing with neurohumoral relationships. In this section David Nachmansohn summarizes the knowledge of the role of acetylcholine in the mechanism of nerve activity, and Frank A. Beach gives a fascinating discussion of the role of hormones in the mating behavior in vertebrates. The second section, dealing with the chemistry and physiology of adrenal hormones, is the most technical in the book, and those who can read it profitably are undoubtedly limited in number. Papers by E. C. Kendall, T. F. Gallagher, C. N. H. Long and Gregory Pincus discuss various aspects of the synthesis and actions of the adrenal cortical steroids.

The role of hormones in metabolic processes is ably discussed by Leo T. Samuels, C. D. Kochakian and W. U. Gardner in the third section. Of interest to clinicians are the excellent discussions of various aspects of clinical endocrinology in the fourth part of the book. Ira T. Nathanson presents a masterly discussion of the role of endocrines in human cancer; Fuller Albright brings up to date our knowledge of the effect of hormones on osteogenesis; Nathan B. Talbot and Edna H. Sobel discuss growth in children and the endocrine factors influencing this process; and Arthur Grollman gives a well balanced picture of our knowledge of the endocrine aspects of experimental renal hypertension.

This book, although of greatest interest to the experimental endocrinologist, can be read with profit by biochemists, physiologists and clinicians who seek authoritative information concerning the newer knowledge of hormones.

A Handbook of Commonly Used Drugs, Including Certain Measures for the Control of Diseases Peculiar to the Tropics of the Western Hemisphere. By Michel Pijoan, B.A., M.D., Director, The Chemical Foundation Laboratory, University of Colorado, Boulder, Colorado, and Clark Harvey Yeager, M.D., Dr.P.H., Chief of the Medical Section, Health and Sanitation Division, Office of Inter-American Affairs, Washington, D. C. Cloth. Price, $3.75. Pp. 198. Charles C Thomas, 301-327 E. Lawrence Ave., Springfield, Ill., 1947.

This book cannot be recommended for students or physicians. There are now available so many books on drugs that there would seem to be little excuse for new ones unless they provide a real contribution. The authors have attempted to provide a small book apparently for occasions "when reference material for drug research is difficult to obtain"; they state that it "is not designed to replace the standard texts in Pharmacology but rather to act as an adjunct and a guide in conditions where such texts are relatively unavailable." Unfortunately, what is offered cannot be considered adequate even as an adjunct and certainly not as a guide. Such important subjects as diuretics are dismissed in two and one-half pages, female sex hormones in one and one-half pages, cathartics with one page and emetics and expectorants with one page. The book is already dated, as there is no mention of newer substances such as "tridione," thiouracil and propylthiouracil, and "promin" for leprosy; the discussion on folic acid is limited to eleven words in a chapter on nutritional factors and omitted entirely from the chapter on hematologic agents. Only diethylstilbestrol seems to be mentioned as a synthetic estrogenic substance and then under the name "stilbestrol," a name which has been discontinued for some time. Furthermore, there are statements which are contrary to the consensus of those informed in the respective fields. For example, strychnine is offered as a stimulant for barbital poisoning, "dilaudid" is claimed to be better than the other opium derivatives, "anthallan" is given a favorable recommendation for pruritus, allergic dermatoses and infantile eczema, and "atabrine" is "now the drug of choice in treating malaria." The authors claim that "the synthetic product desoxycorticosterone has placed the use of cortical extracts in second place. The synthetic product is more effective, more potent, and can be assayed quantitatively." And for agranulocytosis, "pentnucleotide" "may cause a remarkable improvement within forty-eight hours." This is an unusual statement in view of the fact that pentnucleotide has been supplanted as an effective agent for agranulocytosis and the informed workers are now agreed that penicillin is the most effective substance.

Considering the small amount of space that is devoted to drugs, one wonders why pages in this volume are taken up with discussions of tropical diseases that include manifestations, transmission, treatment and prevention, a classification of anemias, as well as a discussion of the blood bank and details of how to test for blood groups. A description of a drug is supposed to reveal what it is, how it works, what it is good for, the dosage and any specific properties that may be of value to the physician, such as incompatibilities and synergism. When these are presented in proper sequence, with sufficient explanation and offered with true statements, the reader will have a worth while book as a guide, provided of course the manuscript is proofread carefully. This book even lacks careful proofreading; obvious mistakes appear on pages 5, 15 and 48.

Better Hospital Care for the Ambulant Patient. Report of the Special Committee on Hospital Clinic Services. Paper. Pp. 184, with 2 illustrations. The Hospital Association of Pennsylvania, 222 N. Third St., Harrisburg, Pennsylvania, 1946.

A survey of outpatient services rendered by voluntary hospitals was conducted by the Special Committee on Hospital Clinic Services of the Hospital Association of Pennsylvania. While the survey was confined to Pennsylvania, the recommendations apply to voluntary hospitals generally. As a study of services and facilities, it is somewhat less detailed than seems necessary. Outpatient clinics and group practice clinics in connection with hospital services are considered in detail. The function of the voluntary hospital in restoring the usefulness of handicapped persons is carefully presented. The health center idea and the problem of dental care are related briefly in terms of hospital services. One is impressed by the committee's evaluation of the voluntary hospital as the center for all voluntary health services. According to the committee "the hospital of the future must not be a single, independent institution, but part of a system of health service, coordinated functionally and administratively with other agencies to provide complete health care to every part of the community." This to the committee does not mean merely provision of hospital facilities and diagnostic facilities. "From its study and investigation of the two types of clinics (diagnostic clinic and diagnostic treatment clinic) the committee is unanimous in the belief that the diagnostic clinic which does not afford treatment, while performing a valuable service for certain types of cases, is not the type of clinic which it can recommend to the serious consideration of most of the member hospitals of the association. The primary reason is that diagnostic clinics by themselves are not popular with the public and are not self supporting.

While the committee does not suggest that hospitals take over the practice of medicine, it goes to some length to show the trend toward group practice. It states that "the establishment of independent group clinics, rather than the establishment of group clinics in close collaboration with the voluntary hospitals, is not in the public interest."

In discussing the group clinics the committee recommends that "under no circumstances . . . should the hospital seek to make a profit out of the clinic." However, it adds that most of the successful group clinics "have provided funds out of the clinic's surplus earnings for the construction of enlarged quarters for the clinic; for the purchase of new diagnostic equipment; for the enlargement and reequipping of the x-ray department and laboratories of the hospital as required, and in many cases for the expansion of the bed capacity of the hospital to take care of the growing business of the clinic."

The committee lists a number of "musts" for hospitals if they are to keep up with the trend of the times. In view of these comments and to help in understanding the hospital group's view of their own future, the following excerpt is interesting: "The necessary step is to teach them (the people) to go to clinics as soon as their bodies warn them that something is wrong, so that they may be cured while they are on their feet, without loss of time at work."

Uterotubal Insufflation: A Clinical Diagnostic Method of Determining the Tubal Factor in Sterility Including Therapeutic Aspects and Comparative Notes on Hysterosalpingography. By I. C. Rubin, M.D., F.A.C.S., Clinical Professor of Gynecology, College of Physicians and Surgeons, Columbia University, New York. Cloth. Price, $10. Pp. 453, with 159 illustrations. C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1947.

This book was written with a twofold purpose. The first was to present uterotubal insufflation in its completed form as a clinical, nonsurgical method of testing for tubal patency and as a therapeutic agent. The second purpose was to evaluate by means of this test the etiologic importance of obstructed uterine tubes in sterile matings. The data presented are based chiefly on the author's extensive experience with uterotubal insufflation, which began in 1919, although his studies on the use of radiopaque substances started in 1914. The book is divided into five parts, comprising (1) anatomy, pathology and physiology of the fallopian tube, (2) technic of tubal insufflation, diagnosis, (3) therapy, (4) comparison of kymographic tubal insufflation and intrauterine injection of lipiodol and other iodized oils and (5) appendix.

Supplementing the author's personal experience are data derived from replies to a questionnaire sent by Rubin on the results of 80,376 tubal insufflations. The safety of this test is proved by the fact that there were only 190 cases of pelvic infection following the 80,376 tests. Rubin says this is "an incidence of 0.0024 per cent," but this is an error. The incidence is 0.203 per cent. Only two deaths from infection were reported from the total number of insufflations performed by 371 colleagues.

This book contains an enormous amount of useful knowledge not only about every aspect of the insufflation test and the use of iodized oil for determining the patency of the fallopian tubes but also about many factors in sterility other than that which concerns the tubes. An extensive literature is reviewed, as evidenced by a list of references which occupies twenty-four pages. Rubin himself contributed forty-five papers on the subject. The illustrations and graphs are beautiful and instructive, and all are well reproduced. The book is easy to read because it is written in a delightful and modest way.

Rubin's incidence of pregnancy in his 3,200 personal cases was over 18 per cent and the reviewer's incidence was more than 17 per cent. However, even if we conservatively estimate the frequency of pregnancy after the Rubin test as only 15 per cent, at least 12,000 women became pregnant after the 80,376 Rubin tests collected by the author. The majority of these women gave birth to healthy babies. If to this number are added the many thousands of unreported successes not only in this country but also all over the world, it will be realized that Rubin's contribution represents one of the great advances in the history of medicine in the last half century.

Quantitative Clinical Chemistry Interpretations. Volume I. By John P. Peters, M.D., M.A., Professor of Internal Medicine, Yale University School of Medicine, New Haven, Connecticut, and Donald D. Van Slyke, Ph.D., Sc.D. Second edition. Cloth. Price, $7. Pp. 1,041, with 62 illustrations. The Williams & Wilkins Company, Mt. Royal & Guilford Aves., Baltimore 2, 1946.

Only one of a projected three volumes of the long awaited second edition of this fine reference work is as yet available. While the first edition was composed of two volumes, it was found necessary in the present edition to present the Interpretations in two volumes, and the Methods in the third.

This first volume, on interpretations, is now available, covering thoroughly the four topics energy metabolism, carbohydrate metabolism, lipid metabolism and protein metabolism. The second part, concerning carbohydrates, contains chapters on chemistry, physiology and the clinical aspects; the third portion contains chapters on lipids, steroid hormones and fat soluble vitamins; and that on protein contains the net metabolism of protein, amino acids, urea, ammonia, creatine and creatinine, and purines and pyrimidines.

Each topic is covered in a manner that allows the available evidence to be presented clearly and then interpreted, evaluated and criticized in a thoroughly scientific manner. By such means the little that is yet known with certainty about the complete course and continuity of any given phase of metabolism and the great amount left to conjecture is emphasized.

The preface states that "the bibliographies are indecently long," but it is in part because of, rather than in spite of, its completeness that this work is so valuable. The information obtained from important articles which were published as late as 1945 have been incorporated in the text.

The book contains good paper and is well bound. The illustrations are neat and clear; the subject index is well organized and appears to be quite complete.

Eksperimentalnaya endokrinologiya: Shchitovidnaya zheleza, parashchitovidnye zhelezy, podzheludochnaya zheleza, nadpochechniki, polovye zhelezy, gipofiz. [By] N. B. Medvedeva. [Experimental Endocrinology: Thyroid Gland, Parathyroid Glands, Pancreas, Adrenals, Gonads, Pituitary Body.] Cloth. Pp. 743. Izdatelstvo Akademii Nauk Ukrainskoy SSR, Kiev, 1946.

This volume, in Russian, is devoted to the consideration of the thyroid, the parathyroids, the pancreas, the adrenals, the reproductive organs and the hypophysis. The present status of our knowledge of the internal secretions of the various endocrine glands is presented in an exhaustive and critical manner. At the same time, problems requiring further investigations are pointed out. The author, herself a prolific worker in the field of endocrinology, presents her own contributions on the cellular functions of the parathyroids and the hypophysis and on the important function of the adrenal cortex in what she terms the reparative phase of carbohydrate metabolism. The isolation by the author of a "hormone of rest" in the secretion of the adrenal cortex opens up possibilities of treatment of certain asthenic states. The volume is a worth while contribution to the literature on internal secretions.

Jubilee Volume Dedicated to Emil Christoph Barell, Philosophiae Doctor, Medicinae Doctor Honoris Causa, Rerum Politicarum Doctor Honoris Causa, President of F. Hoffmann-La Roche & Co. Limited Company, on the Occasion of the Fiftieth Anniversary of His Association with the House of Roche, by the Scientific Workers of the Roche Companies. Cloth. Pp. 468, with illustrations. Hoffmann-La Roche, Inc., Nutley, N. J.; Basel, 1946.

This volume is dedicated to Emil Christoph Barell, president of F. Hoffmann-La Roche & Co., Ltd., on the occasion of the fiftieth anniversary of his association with the house of Roche. It has been compiled by the scientific workers of the Roche companies. Some of the articles are written in German, others in English. They are all concerned primarily with fundamental studies on such subjects as vitamins, antiseptics and analgesics, which are of more interest to the research worker than to the clinician. The laboratory man will probably find considerable interest in the volume because of the nature of the topics and because of his training to evaluate critically this type of material.

The Ethicon Book of Sutures for Operating Room Nurses and Others Interested in the History, Use, and Manufacture of Suture Materials. Compiled by Miriam Zeller Gross, A.B., M.A. Fabrikoid. Price, 50 cents. Pp. 200, with illustrations. Ethicon Suture Laboratories, Division of Johnson & Johnson, New Brunswick, N. J., 1946.

This book is designed for the promotion of surgical gut sutures. It is published by the Ethicon Suture Laboratories, a division of Johnson and Johnson. The most interesting and instructive part of the book occupies about a third of the text. The rest of the material is largely miscellaneous, anecdotal and historical.

Vladimir Petrovich Filtov, laureat Stalinskoy premii: Deystvitelniy chlen Akademii Nauk Ukrainskoy SSR i Akademii Meditsinskikh Nauk SSSR (Kratkiy ocherk zhizni i tvorchestva). [By] S. F. Kalfa i V. E. Shevalev. [Vladimir Petrovich Filatov: Short Sketch of His Life and Work.] Paper. Price, 3 rubles. Pp. 48, with 11 illustrations. Izdatelstvo Akademii Nauk Ukrainskoy SSR, Kiev, 1946.

This is a brief brochure on Filatov and a brief report on some of his clinical contributions.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

RHEUMATOID ARTHRITIS AND VITAMIN DEFICIENCY

To the Editor:—Can vitamin deficiency of itself cause rheumatoid arthritis or is it "only an influencing factor of the disease?" What is the present medical consensus? I ask the question because of my experience with the following case: A housewife, first seen by me on Feb. 1, 1945, had been suffering with arthritis of the hands and feet for twenty-two years, the attacks occurring at intervals of one to three months. There was no fever but much suffering from pain, sleeplessness and impaired function. Her tonsils and teeth had been removed thirteen years previously. She had been treated with diathermy and ultraviolet light without relief. Gold injections had been tried, but she was unable to tolerate them. My examination showed a typical uniform symmetrical picture of arthritis deformans of all the fingers, wrists and toes, carpal and metacarpal, tarsal and metatarsal joints with atrophy of the soft tissues, lateral subluxations and loss of function. Aside from this far advanced and incurable destruction in the extremities, the patient's general condition was fairly satisfactory. Her weight was 130 pounds (59 Kg.), height 61 inches (155 cm.), pulse 80, blood pressure 120/80. Since she had glossitis I prescribed nicotinic acid and riboflavin tablets. Within a week the arthritic attack from which she was suffering at the time of her visit ended. Two months after the beginning of the treatment she stated that she was feeling considerably better generally and had gained 5 pounds (2.3 Kg.). Without further consultation she discontinued the vitamin dosage. Towards the end of April she suffered a new arthritic attack. On May 10 I prescribed large doses of the entire B complex. Since that time, for approximately eighteen months, there have been no new attacks. Her general condition is much improved; her weight has risen to 157 pounds (71 Kg.); her sedimentation rate has dropped from 27 to 17 mm. per hour. There has been slight but noticeable recovery of function of the affected members.

Bendet Nelson, M.D., New York.

Answer.—It has never been shown experimentally or clinically that any vitamin deficiency caused rheumatoid arthritis. Large amounts of the various vitamins have been given to many patients with this disease without significant effect on the joints (Freyberg, R. H.: Treatment of Arthritis with Vitamin and Endocrine Preparations, The Journal, Aug. 8, 1942, p. 1165. Traeger, C. H.: *M. Clin. North America.* **30**:616 [May] 1946).

Minor degrees of vitamin deficiency are not uncommonly found in rheumatoid patients as they are found also in patients chronically ill from a variety of diseases. Such minor symptoms of vitamin B deficiency as mild dermatitis over elbows or knees, sore mouth and red, sore tongue may be found in arthritic patients who have anorexia, chronic indigestion or malnutrition or who have too assiduously adhered to a low calory "rheumatism diet." These lesions respond well to the administration of vitamin B complex or its components, but the articular lesions of rheumatoid arthritis have not responded significantly to the use of vitamin B or of any other vitamin preparation.

There is also no direct indication for the use of vitamins A, C, E or K in the treatment of rheumatoid arthritis. Concentrated doses of vitamin D sometimes provide a temporary sense of well being but are not curative and may be dangerous. Cases of vitamin D intoxication, some fatal, are being reported increasingly as occurring in patients with rheumatoid arthritis.

CONCEPTION AND MENSTRUATION

To the Editor:—Is it possible for coitus during menstruation to result in pregnancy and, if so, what is the mechanism of nidation? Is there any well founded objection to this practice?

M.D., New York.

Answer.—Theoretically and from studies in monkeys, conception is impossible during menstruation. The reason for this is that in both monkeys and women who have a fairly regular menstrual cycle varying from twenty-six to thirty days, ovulation occurs in the midinterval between the bleeding episodes. Ovulation usually takes place about fourteen days before the next expected menses. A female egg does not live more than a few hours, and spermatozoa probably are not capable of fertilization for more than twenty-four hours; hence for pregnancy to occur the ovum and egg must meet within a maximum period of forty-eight hours. However, R. L. Dickinson (*Am. J. Obst. & Gynec.* **14**:718 [Dec.] 1927) studied the "safe period" as a birth control measure from seven different angles: (1) records of pregnancies resulting from isolated intercourse, (2) ovulation as studied at laparotomies or on removal of ovaries, (3) effect on the subsequent period of castrating irradiation given at different days of the interval, (4) studies of the age of very young embryos, (5) types of tubal contraction and alterations in epithelial layers as found in women and shown to occur in animals at egg passing time, (6) hormones in the blood at different times and (7) vaginal smears. Dickinson claimed that there was general agreement on five matters: (1) Conception can occur at any part of the month, (2) there is a definite difference between favorable and unfavorable periods, (3) the week or ten days following menstruation is the time of greatest likelihood of conception, (4) the week preceding menstruation presents the least chance of conception, averaging about 7 per cent, or in various lists 3, 6, 9, 9.3 and 10 per cent, and (5) conception during menstruation is relatively frequent, about 13 per cent. Dickinson says further that, in view of the common avoidance of intercourse during menstruation, the percentage quoted by him may indicate a lower capacity for conception than actually exists.

It is difficult to reconcile Dickinson's statements with known physiologic facts. In at least some cases in which reliance was placed on a single coitus, either the patient's memory was fallacious or she had good reason to tell an untruth. Likewise it may be possible that ova survive longer in women than in animals and also spermatozoa may be capable of fertilization for a longer time.

Except for esthetic reasons there is no objection to having intercourse during menstruation if the flow is normal in amount. However, in women who bleed profusely the practice would be pernicious.

STERILIZATION OF MORGUE IN TUBERCULOSIS SANATORIUM

To the Editor:—Will you kindly advise what is considered the best procedure for sterilizing the autopsy table and morgue floor in a tuberculosis sanatorium?

Raymond H. Goodale, M.D., Worcester, Mass.

Answer.—The problem essentially involves the killing of tubercle bacilli on the autopsy table, instruments and floors of the autopsy room. It must also be remembered that the bacilli are sometimes protected by varying amounts of mucus and purulent exudate.

There are various possibilities, among which may be mentioned the sterilization with live steam, sterilization with ultraviolet light and the free use of saponated solution of cresol (lysol) or similar disinfectant. All these methods have objectionable features. The live steam may not reach every bacillus in crevices. The ultraviolet light also cannot "go around corners." In addition there is much danger of eye damage if lead goggles are not used. The lysol method is effective but greatly overdone; there can scarcely be any necessity to cover the floors with a 1 inch layer of lysol solution.

Until something better is proved by experiment the use of a form of contagious technic with a good disinfectant is indicated. The method of procedure must be more rigid than that usually employed in the autopsy room. It should approach more the technic used in the most contagious of diseases. The operators should be well gowned, should wear gloves and should wear special shoes or rubbers that can be sterilized. There should be great care not to drop any liquid material on the floors, and if any drops of blood or pus accidentally fall to the floor they should be wiped up immediately with a sponge saturated with disinfectant. The aim should be to confine all the septic material to the autopsy table, metal tables and scales, all of which can be readily cleaned with water and disinfectant. When the autopsy is completed, a properly instructed assistant or diener should wash off all the tables and instruments with water, making sure that all the washings go down the drain. Then the tools are to be put in a disinfecting solution and the tables and scales are to be gone over with sponges soaked in disinfectant. The floors are then mopped with disinfectant, care being taken not only that the floor is cleaned but that the disinfectant penetrates all cracks and crevices. When the disinfectant dries it gradually becomes concentrated, and every object is ultimately covered with concentrated solution.

The disinfectant used is of much importance. Certain ones (as mercury bichloride) are precipitated on any albuminous material and are thereby rendered ineffective. The coal tar products and related substances (phenols, cresols) have better penetrating power and are more effective. The ordinary "lysol" is good because of the added clearing properties of the soap. Certain quaternary ammonium compounds seem to offer some promise, but they must be used in rather high concentrations; an added feature is the freedom from the objectionable odor inherent in the coal tar products. Most other tuberculocidal substances are too costly. The fact is that an ideal disinfectant has not yet been found that will be effective, free from odor and inexpensive.

FEEDING OF PREMATURE INFANTS

To the Editor:—Is it the modern practice to have a mother make an effort to nurse her premature 8 month old baby, weighing 5 pounds at birth, and if the mother cannot supply sufficient milk then to supplement it with modified cow's milk? The mother is anxious to nurse her baby. Would the following be a good formula for the baby to start out on: "Straight unpasteurized cow's milk—first remove all the cream, then add sugar (but no water) and boil for about one-half hour at 150 degrees." Feed the baby 1½ to 2 ounces every two hours and three to four hour intervals at night? Is the modern conception to reduce the protein content by adding varying amounts of water and sugar to bring it up to mother's milk and to add cream slowly to bring the fat content up to that of the mother's milk? Isn't it safer and more desirable and convenient to use condensed unsweetened milk to make up the formula?

M.D., Tennessee.

ANSWER.—Breast milk is the best feeding for any premature baby. A premature infant weighing 5 pounds should be vigorous enough to nurse entirely at the breast if the mother has a sufficient milk supply. If the mother's milk is insufficient it would then be necessary to complement the breast feedings with modified cow's milk formula. This can be done either by diluting whole cow's milk with water and adding a carbohydrate such as dextrose, lactose or cane sugar up to approximately 5 per cent of the total volume, or using an already prepared commercial cow's milk feeding, either powdered or liquid, with proper dilution. The suggested feeding in the question "Straight unpasteurized cow's milk—first remove all the cream, then add sugar (but no water) and boil for about one half hour at 150 degrees" would be low in fat, and the infant would probably be hungry on such a mixture because of the low caloric value of skimmed milk. As to the intervals of feeding, such an infant could probably be fed at most every three hours, making eight feedings for twenty-four hours. On reaching 6 pounds the baby could probably be given six feedings at four hour intervals. The amount at each feeding would vary with individual infants.

A modern concept of infant feeding attempts to include a sufficient caloric value per ounce together with ample amounts of protein, fat, carbohydrates, mineral salts, water and vitamins, so that all the infant's nutritional needs for growth, development and maintenance are supplied for twenty-four hour feedings. Cow's milk contains 4 per cent protein, as against 1.5 per cent protein in breast milk; dilution with water reduces the protein content of cow's milk but also reduces the carbohydrate content, which at 4 per cent lactose is originally lower than the 7 per cent lactose of breast milk; adding up to 5 per cent carbohydrate brings the caloric value of cow's milk formula up to that of breast milk. There is no reason for skimming the cow's milk or adding extra cream.

The final query dealing with condensed unsweetened milk is not clear. Condensed milk is fresh milk which has been heated for a considerable period, and carbohydrate added for a preservative. Evaporated milk is fresh milk which has been heated so that approximately one-half the volume of water has been removed and no carbohydrate has been added. The term condensed unsweetened milk used in this question probably applies to the modern term evaporated milk, which can be used as a source of cow's milk for the infant's formula. When evaporated milk is used, more water must be added to bring the cow's milk back to its original content, and an additional amount of water used for dilution.

Finally, when cow's milk formula is used in addition to breast milk, the term "complemental feeding" is used for the cow's milk formula from the bottle given directly following a breast nursing. The term "supplemental feeding" is used when the breast feeding is entirely omitted and the infant is given only the bottle formula.

BURNING SENSATION OF TONGUE

To the Editor:—I have in the past two years seen 2 patients, a woman of 60 and a man of 52, whose chief complaint is a burning sensation of the tip of the tongue. There is nothing visible on inspection. Both patients are perfectly normal in other respects. Vitamin deficiency has been ruled out and yet vitamin therapy did not lead to any improvement in their symptoms. Gallbladder disease has also been ruled out.

A. M. Spindler, M.D., New York.

ANSWER.—A burning sensation may occur in the absence of obvious cause, and it may be difficult to find the etiology. Even inflammation may be present but not visible. One must consider the possibilities and then try therapeutic tests. The duration of the burning and the dental situation were not mentioned by the inquirer but may be important.

Inflammation and irritation are often causative. Rough or unclean teeth and dentures may produce irritation at the tip of the tongue. A low grade infection can occur without redness but with soreness and burning of mouth surfaces. Smoking, food or drink may irritate the tongue. Electrogalvanic currents from metal fillings are now considered as credible a cause as when first described.

The tongue mirrors the condition of the intestinal tract to some extent, but the atrophy (with hypoacidity) and catarrh and hypertrophy (with hyperacidity) are usually visible and are not regularly accompanied with burning.

Deficiencies may produce tongue changes, but they are usually visible. Subclinical lesions may come from the lack of several members of the vitamin B complex and are not always cleared by therapy. The absence of the intrinsic factor, as well as an iron deficiency, may produce a superficial glossitis and atrophy which clears on therapy.

A neurogenic cause is possible, especially in the age group mentioned. The location makes a nerve lesion improbable. Burning is the common symptom of the temporomandibular syndrome, a result of occlusion changes from tooth wear and gingival shrinkage. Headache and other symptoms of the syndrome should be present. A psychoneurotic condition, perhaps associated with the climacteric, may include burning of the tongue.

A red blood cell count and a determination of gastric acidity might give valuable information. Appropriate treatment could then be used, if indicated.

Other methods of therapy might include cleaning and smoothing of the teeth or denture, a decrease in smoking and the use of irritant food and drink, the use of an astringent mouth wash (containing zinc chloride) and a trial of penicillin troches. Since vitamin therapy has failed so far, only unusual methods would seem worth a trial. Sevringhaus has reported clearance of chronic mild stomatitis from the administration of large oral doses (50 mg.) of nicotinamide over a two to three week period.

WIDESPREAD BURNING SENSATION

To the Editor:—What would cause burning of the soles of the feet, the palms of the hands, the eyelids, face and rectum, in presence of normal blood and urinary findings, in a man aged 45? What therapy can be suggested?

Edmund R. Nightingale, M.D., Bronx, N.Y.

ANSWER.—It is difficult to make a diagnosis on the data supplied. Acroparesthesia and acrodynia are terms given to an ill defined syndrome of a burning sensation in the extremities, possibly due to vitamin deficiency. Conceivably a similar process might affect the face and rectum also. An allergic state might be considered. In many cases of generalized itching and burning there is a psychiatric background.

A high vitamin diet especially rich in pantothenic acid may be tried, if this has not already been done. Injections of liver extract, as for pernicious anemia, might be tried also. The use of benadryl is sometimes of value in itching and burning of allergic origin. A psychiatric investigation, or possibly the use of the Rorschach test, might be helpful in uncovering neurotic trends.

ASYMPTOMATIC NEUROSYPHILIS

To the Editor:—A professional man aged 42 has for the past thirteen years had a 2 plus blood Wassermann reaction. Reports of spinal fluid tests made in 1940 and 1943 are not obtainable. About ten days ago the patient had a spinal fluid test revealing the cell count 0, colloidal gold 001222100 and quantitative Kolmer 44310. He has been examined by another internist and myself and our findings as to his physical condition are negative. He has had a thorough neurologic examination, which also was negative. The other internist interested in the patient's welfare suggested that we give the patient 10,000,000 units of penicillin. Eighteen months ago I gave him 4,000,000 units of penicillin, thirty-six oxophenarsine hydrochloride and twenty-four thiobismol treatments, and the Wassermann reaction remained 2 plus. A spinal test was not made at that time. It is my suggestion that the patient, if given penicillin at this time, have insulin or malaria along with it. There is a doubt in my mind as to whether the patient should have any treatment at present.

R. M. Nicholson, M.D., Los Angeles.

ANSWER.—In view of the fact that previous treatment of the patient for syphilis has been adequate according to accepted standards and that the present physical findings are negative for evidence of the disease, the decision as to the future handling centers about the significance of the spinal fluid examination just obtained. If the results of the spinal fluid studies done in 1940 and 1943 are not obtainable, the first indication is to check the present study. Experience has shown that single spinal fluid examinations are much less reliable than single blood tests in that, particularly in "asymptomatic neurosyphilis," interlaboratory check is much more difficult. It would be unwarranted, therefore, to enter into additional prolonged courses of therapy including malaria on the basis of these observations alone. In interpreting the other spinal fluid findings given it would also be helpful to have total protein determinations performed on the fluid with subsequent tests.

Assuming that the positive spinal fluid reactions given are confirmed, their significance is the next consideration. Syphilis, if present, is of long standing in this case. Under the circumstances the likelihood is not great that the blood serologic tests will be reversed to negative by additional therapy. Time alone without treatment would be as likely to accomplish this. Provided the spinal fluid blood count was performed within an hour or two after the fluid was drawn, the fact that there were no cells seems to indicate little or no activity of the central nervous system infection. In just the same way as there can occur fixed positive bloods, so also can there occur fixed positive spinal fluid Wassermanns in the absence of an actively progressing disease. Under such circumstances additional therapy is not indicated but rather prolonged observation, as in all cases of treated seropositive late syphilis.

If further treatment is decided on, penicillin alone in a total dosage of about 10,000,000 Oxford units, as has been suggested, is probably as satisfactory as any mode of approach to the type of problem that is described. This could be given in the form of aqueous crystalline sodium penicillin 80,000 units every three hours day and night for a period of fifteen days (120 injections), a total of 9.6 million units. Penicillin alone has given results as far as can be told in the period of observation as satisfactory as other forms of therapy, including intraspinal and malaria, for all forms of neurosyphilis with the possible exception of symptomatic dementia paralytica. In a field the study of which is as recent as the penicillin therapy of neurosyphilis there is of course still much difference of opinion, and a perusal of these two articles is suggested as being most pertinent to the therapy of the type of case in question:

Stokes, J. H., and Steiger, H. P.: Penicillin Alone in Neurosyphilis, THE JOURNAL, May 4, 1946, p. 1. Moore, J. E., and Mohr, C. F.: Penicillin in the Treatment of Neurosyphilis: I. Asymptomatic Neurosyphilis, *Am. J. Syph., Gonor. & Ven. Dis.* **3:** 405 (Sept.) 1946.

The use of insulin for malaria, considering the risks involved, hardly seems justified in the absence of symptoms and with spinal fluid findings which do not indicate activity or progression. Suspected cases of neurosyphilis should be completely reevaluated every six months or a year over a period of several years until the exact status can be determined. In fact, the potential seriousness of this complication makes periodic checks for life desirable. Future handling other than suggested will depend on the results of the periodic study.

BARTHOLIN CYST

To the Editor:—A woman aged 37 had a painful cyst about the size of a walnut in the Bartholin region on the right side. On aspiration I found a purulent fluid. After aspiration I injected 100,000 units of penicillin in saline solution into the cyst. Although it is definitely not of gonorrheal origin from the clinical and laboratory point of view, I injected 100,000 units of penicillin in oil on two successive days into the buttocks. Now, two weeks after the aspiration and penicillin treatment, the cyst is flat and about one fifth of its original size and no longer painful at all. The patient has had chronic ulcerative colitis for the past twelve years with occasional acute exacerbations. For the past few months her colitis has been relatively quiescent. Would operative procedure be indicated for this cyst in view of the close proximity between the surgical and the colitis areas or would a more conservative means of treatment be preferable?

S. J. Weitzen, M.D., Bronx, N. Y.

ANSWER.—If the patient has no disturbing symptoms, the greatly reduced Bartholin gland cyst may be left alone. Perhaps during the next few weeks it will shrink still more, but even if it does not there is no need to remove it at present. If the cyst should return and certainly if evidence of infection appears, the cyst should be removed notwithstanding the history of colitis. A Bartholin cyst or abscess may be removed satisfactorily by means of an electric cautery as well as by surgical excision.

NEON LIGHTS

To the Editor:—Will a dermatitis result from a neon light such as used in advertising signs? What are the laws controlling neon lights in relation to the power of the light and the proximity of homes? Are there any harmful effects from such lights?

E. S. Coster, M.D., Solomons, Md.

ANSWER.—In the manufacture and repair of the neon type of signs certain chemicals may be employed that are potentially detrimental to workmen. Such risks do not extend to the public. Most cities and possibly states apply regulations as to signs, but these deal chiefly with dimensions, elevations and supports rather than with light intensities. Zoning ordinances often regulate signs including illuminated signs as an aspect of the noninvasion of residential districts by business. All states and many municipalities possess nuisance laws which may be applicable to illumination as a nuisance. However, neon signs are not nuisances per se and many are not nuisances in any legal sense. Some neon type signs do provide affront to the eyes, to sleep and to safety. Nowadays the eyes are confronted with possibly a hundred times as many varied stimuli as they were half a century ago. Eyes are endlessly beset in their continual efforts to accommodate to changing light stimuli. Complex on and off signs close to the viewer are the most disturbing. Some signs have a high frequency flicker probably related to the form of power. Eyestrain from multitudinous signs is inescapable. Confusion in detecting traffic light signals in the midst of scores of other colored signs jeopardizes safety.

PASTEUR TREATMENT FOR RABIES WHEN NOT BITTEN

To the Editor:—A girl aged 5½ years was exposed to rabies in June 1946. She received the usual fourteen dose Pasteur treatment. About the first day of February 1947 the girl's dog developed signs of rabies, and the diagnosis was pronounced by a veterinarian. Although the girl was not bitten by the dog should she be given another fourteen dose Pasteur treatment?

Karl H. Kortheuer, M.D., Calexico, Calif.

ANSWER.—If the girl was not bitten by the dog, as stated to be a fact in the question, then there is no reason whatever for giving her a new course of treatment now. It is assumed that no open places on her skin or lips came into close contact with the dog's saliva after it became rabid. The same answer would be made if the girl had not been "exposed to rabies" and given preventive treatment last summer. Undoubtedly there is still a degree of immunity as a result of that treatment. It is possible that treatment again at this time might cause undesirable reactions on account of the sensitization induced by the treatment last summer.

FOLLICULAR LYMPHOBLASTOMA

To the Editor:—Will you please discuss the prognosis and treatment of giant follicular lymphoblastoma (Brill-Behr-Symmer's disease).

Aaron Berger, M.D., Bronx, N. Y.

ANSWER.—The prognosis in follicular lymphoblastoma is better than in other types of lymphosarcoma. Baggenstoss and Heck (Follicular Blastoma, *Am. J. M. Sc.* **200:** 17 [July] 1940) collected data on the duration of the disease in 53 cases of follicular lymphoblastoma. The average duration of life in 24 patients who were living was 4.6 years, and in 29 patients who had died it was 4.8 years. Two patients were still living after seventeen years. Most cases of follicular lymphoblastoma respond well to x-ray treatment, at least temporarily. Either local or total body irradiation may be employed (Sugarbaker, E. D., and Craver, L. F.: Lymphosarcoma, THE JOURNAL, July 13, 1940, p. 112). Radioactive phosphorus or nitrogen mustard may produce a therapeutic effect, but x-ray therapy is to be preferred.

SYNTHESIS OF PENICILLIN

To the Editor:—With reference to the inference in the Dec. 21, 1946, issue of The Journal that du Vigneaud and his associates were the first to synthesize penicillin, I would point out that this was first accomplished by Robinson and his co-workers at Oxford by the method given a year or so ago.

Dr. J. A. Marriott, Loughborough, Leicestershire, England.

ANSWER.—According to available records, d-penicillamine hydrochloride was synthesized on Oct. 4, 1943 by Robinson and his co-workers. 2-Phenyl-4-ethoxy-methylene-5 (4) oxazolone was synthesized on March 14, 1944 by Robinson and his co-workers. 2-Styryl-4-ethoxymethylene-5 (4) oxazolone was condensed with dl-penicillamine on March 27, 1944 by Robinson, and this product had slight antibiotic activity. Robinson obtained evidence of active synthetic penicillin in mixtures of dl-penicillamine and 2-benzyl-4-methoxy-methylene-5 (4)-oxazolone seeded with natural penicillin on Nov. 26, 1945, but the Group at Merck's reported the first synthetic preparation to have antibiotic activity on Feb. 29, 1944 (one month before Robinson's group).

Since all groups were exchanging information, one group cannot claim priority in synthesis.

Du Vigneaud's role in the synthesis of penicillin was to demonstrate that the active material detected in the reaction mixtures prepared by the Merck group and by the Oxford group actually contained penicillin. This was done by (*a*) comparison of "antibiotic spectrums" of synthetic and natural material (report of March 1, 1945), (*b*) isotope "tracer" technic (report of Nov. 1, 1945) and (*c*) preparation of "concentrates" of synthetic material by "countercurrent distribution" technic (report of Dec. 15, 1945).

EFFECT OF FASTING ON BLOOD CHOLESTEROL

To the Editor:—When doing a quantitative blood cholesterol in a case of probable hyperthyroidism (with a metabolic rate of plus 31) should the blood be taken on a fasting stomach or not? I understand that fasting causes an increase in blood cholesterol, whereas in hyperthyroidism one would expect a decrease. If the case shows all the usual clinical symptoms of hyperthyroidism and if the metabolic rate is high and the blood cholesterol (fasting) is high is one still justified in making a diagnosis of hyperthyroidism in spite of the high blood cholesterol?

Eugene C. Lowe, M.D, Miami, Fla.

Answer.—Studies by Kartin, Man, Winkler and Peters demonstrated that in two days of complete starvation the concentration of cholesterol increased significantly in only a few of their subjects However, periods of fasting long enough to produce ketosis will cause elevation of the serum cholesterol

In hyperthyroidism the average concentration of serum cholesterol is below normal, but there will be many instances of normal values The finding of a higher than normal concentration of serum cholesterol should make one examine the other evidence for hyperthyroidism carefully but does not absolutely exclude that diagnosis

It is customary but not essential that the patient be fasting when blood is drawn for serum cholesterol determinations.

LEAD SOLDER IN OFFICE STERILIZER AND LEAD PLUMBING

To the Editor—I had recently repaired a small office sterilizer measuring about 13 by 5 inches and noticed a solder used to stop leaking, which appears to contain lead. I should like to know if there is any danger of lead contamination in sterilizing instruments, especially syringes and needles used for parenteral purposes in such sterilization I understand plumbing used for drinking water is constructed with precautions against lead poisoning.

M D, New York.

Answer—The sterilization of instruments or syringes in an office sterilizer repaired against leakage by means of solder which contains lead will not give rise to the risk of introducing significant quantities of lead into the tissues of patients. Traces of lead will be deposited on such equipment, however, and in the case of syringes such traces may react to produce flocculation in injected preparations or solutions which can react with lead salts. Samples of blood or other body fluids taken for analysis for lead (for diagnostic purposes) by means of syringes sterilized in such equipment will also be too greatly contaminated to yield useful results.

Pipes and accessory equipment used for storing or carrying drinking water, as supplied by reliable manufacturers or dealers in the United States, are generally but not always substantially free of lead compounds Careless installation of such equipment, or repairs made by uninformed or careless persons, may introduce lead-bearing materials in the form of lead pipes, solder and joint luting compounds

THE VOICE AFTER REMOVAL OF CANCER OF VOCAL CORD

To the Editor—A white man aged 44, who had just returned from naval service, had a carcinoma of the right vocal cord. This was removed in toto along with the arytenoid. At present he is able to phonate, but his voice can be heard only at a distance of 10 feet in a quiet room. He is a lawyer in civilian life, and his future depends on his ability to talk before a jury without too much difficulty. Do you know of any one who has solved this problem? I thought it might be possible for him to use a contact laryngeal microphone similar to the type used in aviation intercommunication, along with a small type of public address system. Do you know of any one who makes this type of instrument? The instrument, if at all feasible, should be portable.

M D, Missouri

Answer.—A more usable voice might be achieved by one or more of the following means: 1. A careful laryngologic examination might suggest means for improving the shape and action of the scar tissue vocal cord which formed subsequent to the operation. 2. Voice training might prove helpful. Many of the universities now have teachers, specialists in this work, who could perhaps strengthen the voice by appropriate training. 3. The Wright Electro-Larynx (made by the Aurex Corporation of Chicago) is an electrical vibrating device which is placed against the larynx and the sounds produced are articulated in the usual fashion. Such a device might be helpful. However, the noise produced directly by the instrument is usually objectionable. 4. A lip microphone of the high fidelity type being used in naval aviation with suitable amplification might be satisfactory. This type of microphone is not sensitive to outside noise and has proved to be much better than the old style of laryngeal microphone.

EXCESSIVE BODY HAIR

To the Editor.—Is there any effective treatment to prevent or remove excessive hair on the bodies of women? I have seen several young girls with large amounts of long dark colored hair over the abdomen, back or hips. These girls are definitely handicapped. Is there any treatment, endocrine or otherwise, that will prevent or change this condition?

William M Bell, M D, Detroit

Answer—Although the information given is meager it is assumed that the questioner is not referring to (1) cases of extensive hairy nevi of the bathing trunk type or (2) cases of hypertrichosis associated with basophilic hypopituitarism (Cushing's syndrome) or adrenal cortical tumor. Authorities are in general agreement that if the latter two conditions are eliminated from consideration little can be expected from any treatment on an endocrine basis. It should also be mentioned that the use of x-rays to remove superfluous hair should not be resorted to.

If the amount of hair is not too great or the caliber too fine and it is considered sufficient handicap to indicate treatment, electrolysis may be employed with good results and without scarring, but in the areas mentioned it would seem that the end would hardly justify the tediousness of the procedure. If the amount is considerable and the caliber fine, the wax depilatories may offer the best results even though their effect is but temporary. Contrary to popular belief there is no evidence that the repeated use of such preparations will coarsen the hair, and it is possible that the reverse may be true.

COOLEY'S ANEMIA

To the Editor.—Will you please be kind enough to inform me if splenectomy is still being carried out in Cooley's anemia? Are there any specific measures employed? Are x-rays to the spleen used? Is iron of any value?

John A Ianacone, M D, Paterson, N J.

Answer—Splenectomy is of little benefit in the treatment of Cooley's anemia; some authorities feel that this procedure is contraindicated. The operation is followed by an increase in normoblasts in the peripheral blood, but the anemia is unaffected No specific form of therapy, including iron, has been of any help in this disease. X-ray therapy is of questionable value and at best is followed by only transient effects.

HYPERTENSION FOLLOWING BENADRYL

To the Editor.—In Queries and Minor Notes in The Journal, March 15, 1947, M D, New Jersey, reports the development of hypertension in a hay fever patient aged 49 which responded to medical care and rest. During the past year benadryl had been prescribed, and though the patient was relieved of the hay fever he developed a blood pressure of 192/120 Apparently withdrawal of the drug brought about a lowering of the blood pressure to 140/80. The question raised is whether or not hypertension can be produced as a side reaction from the use of either benadryl or pyribenzamine. The reply by the editor is that "it is definitely not the customary action of either benadryl or pyribenzamine to produce a hypertension." Permit me to report that benadryl produced a similar rise in blood pressure in one of my hay fever subjects—a man aged 55—who received ragweed injections preseasonally and seasonally for many years with good results but who was given benadryl in the summer of 1946 for possible added relief. He developed severe headaches and a rise in blood pressure of 200/110. Following withdrawal of the drug the blood pressure returned to his usual level of 138/85. The patient refused to try pyribenzamine. A colleague, following my report of this case at a medical meeting, informed me that he has heard of a similar untoward reaction resulting from benadryl. Thus there are now 3 cases of a transient hypertension resulting from benadryl. I hesitate to account for this reaction. Further studies should be indicated to explain adequately this type of untoward reaction following the ingestion of this antihistamine drug. Apparently similar reactions have not been reported in connection with pyribenzamine.

GRADUATE EDUCATION IN ANESTHESIOLOGY

E. A. ROVENSTINE, M.D.
and
E. M. PAPPER, M.D.
New York

Logic and experience have brought the conclusion that a medical teaching institution must change its prescribed methods of instruction occasionally. Institutions attempting to provide educational exercises in anesthesiology to meet the needs of potential specialists in this branch of practice have found that such changes are required frequently.

There are good reasons for the many alterations in procedure of teaching anesthesiology, originating from the errors of the past, the pressing need to keep abreast of current developments within the specialty and the task of meeting the requirements of the unprecedented advances of surgery. Other circumstances have complicated the efforts to establish and maintain adequate educational facilities to meet the increasing needs of anesthesiology. New drugs and methods have been accumulated rapidly, the scope of practice has been enlarged and the acute shortage of competent teachers has become pointedly evident. These considerations have served to confuse those who have taken the initiative in planning the development of the infant specialty. They have forced frequent evaluation and reevaluation of methods for teaching, many changes and no immediately predictable solution to many problems.

The serious study of teaching philosophies and technics in anesthesiology as well as in other intellectual disciplines necessitates an appraisal of past methods, a critical evaluation of present habits and an imagination which can anticipate the needs of the future. Inquiry into the early development of the specialty presents a valuable guide in understanding how things came to be what they are and in determining the errors that have been handed down ensconced in the protective halo of "tradition."

DEVELOPMENT OF THE SPECIALTY

In the earliest days of anesthesia the art of administering ether, chloroform and nitrous oxide was considered knowledge that was a mysterious property of the possessor and, of course, teaching was nonexistent. Gradually the concept that the management of anesthetic drugs was not a personal attribute but a legitimate phase of the care of surgical patients was acquired. scop[illegible] preceptor system was then inaugurated rather naturally and spontaneously in the manner of the other disciplines of medicine. However, it seems apparent [illegible] or no effort was made to do anything more than "pour ether." Our surgical forebears practicing at the turn of the present century can be forgiven readily if they considered this type of anesthesia as unworthy of and not requiring the skill of a physician. When anesthesia became purely a technical exercise requiring no judgment and moderate manual dexterity the utilization of anesthetic drugs was properly the province of technicians. Nurses were the logical personnel for this task and they were trained by physicians and then by one another in the technical aspects of rendering patients unconscious for surgical manipulations, a type of teaching that has persisted to the present, althougn its position in modern medicine is an anachronism. Despite the ascendency of the technician, anesthesia was not completely abandoned by the medical profession, but the quality of the efforts of physicians was highly unsatisfactory. The general practitioner not infrequently became an anesthetist either for want of some one better trained or more often as a means of supplementing an inadequate income. His interest in anesthesia was consonant with his skill as a rule, reflecting discredit or apathy on anesthesia as a special practice in medicine. The young physician member of the hospital house staff was no improvement over his elders. Anesthesia in some hospitals was delegated to the least experienced intern, who learned what little he could from his predecessor, greatly relieved to relinquish his undesired assignment. There is small wonder that understanding of anesthetic problems languished under such circumstances and that surgeons were more comfortable with a nurse performing anesthetic tasks. At least she didn't regard her work as an unwanted chore!

In the second decade of this century physicians with a prophetic interest in anesthesia emerged on the scene. These men learned anesthesia by actual performance in the operating theater, by careful observation of the responses of patients and by logical deductions based on their own experience. When clinical observations were inadequate in coping with practical or theoretical problems, assistance was requested and obtained from the laboratory. The value of scientific research was grasped quickly and produced the understanding that the infant specialty had tremendous potentialities for the improved care of patients, the acquisition of knowledge of biologic processes, the methods of their modification by drugs and a worthy intellectual discipline per se.

However, it can scarcely be stated that the first American anesthesiologists, in the full sense of that word, were taught anesthesia in any fashion approaching orthodox pedagogic principles. Rather must it be emphasized that they learned of themselves. This group became the first self-proclaimed specialists in anesthesiology, and the specialty owes them much for their contributions and more particularly for their interest in

---

From [illegible]e Department of Anesthesia, New York University College of establishing anesthesia as a science and indoctrinating others with their habits of thought as well as the fruits of their knowledge.

In the era when modern anesthesiology took root, teaching was still very primitive. The attitude toward training was exceedingly naive. It was still considered adequate to have a student spend a few weeks with a preceptor or in a short course which was entirely devoted to the mastery of agents and other equipment in the operating room. To put it baldly, physician anesthetists were trained as technicians still, despite the fact that they were graduates in medicine and presumably were qualified to think in scientific terms and exercise clinical judgment.

THE WORK OF FRANK H. MC MECHAN

Although the practice of anesthesiology in some areas was vastly improved much earlier, systematic educational efforts are very recent and not widely adopted. Probably the earliest significant effort in gaining recognition for anesthesia in medicine was that of Dr. Frank H. McMechan, who organized a group of physicians interested in the specialty in the second decade of this century. The organization, which later became national and finally international in scope, together with its publications, is a permanent tribute to the tireless skill of Dr. McMechan in establishing anesthesia as a science and teaching it to younger physicians. The subsequent organization of the American Society of Anesthesiologists on a national scale represented the gathering of like minded physicians to further anesthesiology as a specialty. The educational consequences of this type of organization were readily apparent. Physicians exchanged information and experience about anesthesia informally and in the dress of meetings where information was formalized in the clinical or scientific paper. The publication of the journal *Anesthesiology* by the society provided additional educational opportunities. The establishment of the section in the American Medical Association and the inception of the American Board of Anesthesiology served to focus attention sharply on the necessity of requiring definite standards in knowledge and ability as prerequisite to the approved practice of the specialty. The participation of the Council on Medical Education and Hospitals in the problem of training physicians in the specialty proved a great aid. Residencies were approved for teaching after careful investigation of their facilities. Standards in teaching were therefore elevated, and the prospective anesthetist had available to him the information he required when he sought graduate instruction. The implications for the education of the future anesthetist became clear in principle, although the actual methods of providing this training were and are still decidedly fluid in character.

IMPORTANCE OF THE RESIDENCY

The principle established in the teaching of anesthesia by the standards set forth is founded in the residency, the prototype of graduate education in all other clinical specialties of medicine. Although the system of resident training is well established in all special branches of medicine, its true purpose and the position of the resident are frequently confused. The residency, when properly designed, consists of a careful instructional program which is destined to inculcate into the student independence of judgment, adequate theoretical knowledge and consummate technical skill. This is not a preceptor type of training in that the resident does not learn by imitation of his teacher or necessarily follow in his footsteps. He is taught all aspects of anesthesiology, with particular stress on the concept that his specialty is dynamic and that the procedures of today may be entirely changed tomorrow. If his education is such that flexibility and imagination become incorporated into his professional development, he is a fit product of a good residency. It must be emphasized decisively that the residency or the fellowship is fundamentally and primarily an educational experience for the incumbent and is not designed chiefly for the functioning of a department or even the care of patients in a hospital. These are necessary by-products of the residency but not the essence of its character. It is, of course, mandatory that a residency provide suitable clinical material for instruction and experience and also indoctrination in the basic sciences related to anesthesiology that is thorough and secure.

Much lip service has been rendered to the teaching of the fundamental sciences and little has in actual practice been performed. It has been stated in a careful and painstaking survey of graduate medical education[1] that these requirements can be met effectively by universities or by hospitals or groups affiliated with colleges of medicine or conducting medical programs on the same plane of scientific activity. The graduate of a residency conducted as an educational project will be a specialist of good clinical judgment, proficient technically and endowed with either an appreciation of the fundamental sciences or actual research experience in these fields. Unless the residency system can produce this type of specialist, it has failed in graduate medical education.

INSTRUCTION DURING THE WAR

The entrance of the United States into World War II seriously altered the entire philosophy of teaching in anesthesiology so radically that the full implications are not thoroughly grasped even today. The residency system was disrupted in its major aspects by the needs of the armed forces for medical personnel, and even so the supply of anesthesiologists was wofully inadequate. To meet the emergency, instructional plans were instituted in various military hospitals and in several universities and medical centers. Medical officers were assigned as students for periods ranging from several weeks to months. Most courses were given for three month periods. Even under ideal circumstances this type of training could not, by present standards, be sufficient for the development of specialists in anesthesia. It is to the credit of the officers graduated from these courses and their teachers that anesthesia practice in military life permitted the medical department to discharge its mission, but the training and ensuing professional activities were essentially stop-gap procedures There is little doubt, however, that interest in a thesia developed in many of these students and surgical confrères if one can judge by the rath number of veterans who have sought more t instruction in anesthesia after discharge fr services.

POSTWAR DEVELOPMENTS

In the postwar period the teaching of anesthesiology requires enormous versatility because of the manifold and divergent problems which are unsolved. The training of veterans who obtained their initial experience in the specialty in military service is an obligation which cannot be ignored by teaching institutions, and this is a task of tremendous proportions. Closely correlated with the indoctrination of individuals in anesthetic skills is the moral requirement to furnish competent anesthesia to patients in veterans' hospitals. Fortunately, the professional control of many of these institutions is supervised by medical schools and their faculties, with the possibility of conducting adequate teaching programs for the physicians on full time basis in the Veterans Administration. Great care must be exercised, however, in providing much more than the perfunctory stamp of approval by a university faculty in the veterans' or military hospital. Teaching on a par with academic standards is a goal which must be attained.

American anesthesiologists are also confronted with the necessity of thinking in global terms perhaps more than our colleagues in other specialties, since the extended development of anesthesia is not worldwide. Knowledge of even basic tenets in anesthesiology is absent on much of the European continent and in the Orient because of the devastation of war and the prolonged period of domination of European medicine by the sterile Nazi philosophies. It seems necessary that provision be made within the framework of the pertinent United Nations committees and directly by American teaching centers for the training of many foreign physicians in anesthesiology in the United States.

It is clear, then, that the coming of age of anesthesiology, the great demand for competent specialists and the appalling shortage of qualified anesthesiologists necessitate a program of training which must be wider in scope than anything planned heretofore. The opportunity for a satisfying and mature professional life in the specialty demands groups of students of a caliber equal to that in other branches of medicine. Many more residencies on the graduate level, in the full sense of that word, are required to discharge these obligations. Of necessity the colleges of medicine and other teaching medical institutions will not have fulfilled their responsibilities completely until satisfactory teaching activities are established for anesthesiology and other specialties in which the demand overwhelms the possible supply. This situation will exist for the foreseeable professional lifetime of most of us.

THE TRAINING AT NEW YORK UNIVERSITY

The responsibility for training anesthesiologists has been keenly felt and willingly accepted at New York University in collaboration with its affiliated hospitals. From the residency in its simplest form and with a handful of incumbents, the department has grown in numbers and stature to include educational opportunica for graduates in medicine in keeping with the attiscop developed as the specialty grew. It is necessary natu out that teaching plans do not burst on the discer n full bloom but are the results of painstaking ently painful evolutionary experiences.

sidency has been and will undoubtedly con- be the bulwark of graduate education as we d it. Residents are carefully selected on the previous achievement as undergraduates and interns and an estimate of their probable abilities in anesthesiology. The process of selection cannot be overemphasized if physicians of real ability are to be educated on a graduate level. The resident is taught all varieties of clinical anesthesia, nerve blocking and inhalational and parenteral therapy under competent supervision for two years in most instances and three years for others who show promise of conducting independent investigations or becoming directors of hospital departments. Students whose interests and achievements point to academic work are affiliated with the department for longer periods. Most of the residents are intimately associated with at least one investigational project being conducted by members of the permanent staff of the university. At the present time there are twenty-seven physicians receiving such graduate training in the hospitals affiliated with New York University.

An extremely important technic of graduate education is the staff meeting or staff conference. The department conducts two such meetings weekly. The elder and more firmly established of these is an evening meeting which is open to all interested physicians in the community but is designed primarily as a teaching experience for the resident staff. The agenda are arranged by a senior resident and the meeting is conducted by the director. An important paper of interest to anesthesiology is presented by a resident, and discussion is carried on by the director. Current cases of interest are then described by the residents, and comments and criticism emanate from the resident staff, the director and members of the university faculty. Discussion is lively and often controversial. Exposure to and participation in this type of scientific conclave is valuable to the resident staff in the acquisition of new knowledge per se, the airing of opinions of physicians of greater experience and in learning the technic of organizing case material and presenting it to a critical and well informed audience.

The other weekly exercise is more recently established and is for the resident staff exclusively. It occupies three to four hours and is arranged by the students under the supervision of a member of the university faculty who attends the meeting as a moderator and guide to discussion. Approximately half the meetings are devoted to the maintenance of a Journal Club, which includes all the basic science and clinical periodicals related to anesthesiology. Each resident summarizes, for the group, the papers of interest and importance to the specialty, and questions and discussions are enjoyed freely. Since the atmosphere is extremely informal, all points of issue are elaborated on thoroughly. This period also serves as a medium for ward rounds, radiographic review of interesting films, the review of topics and problems of concern to the residents and the demonstration of new or difficult technics in nerve blocking or other phases of anesthesia.

In addition to the residency program for the training of specialists the Department of Anesthesia includes in its activities an extensive postgraduate course of instruction for physicians already engaged in anesthesiology. The course was originally designed to meet the needs of physician veterans whose specialty education was abbreviated by the war or whose instruction had been substandard because of the disruption of teaching facilities during that period. It became evi-

Hemorrho
1931, p.

dent, with early experience, that this educational project was flexible enough to provide practicing or prospective specialists with information of the newer advances in anesthesiology and the pointed relationship between the basic sciences and clinical anesthesiology.

The major course of didactic instruction is conducted five afternoons a week for a period of six months. The teaching load is carried by the regular members of the faculty of the Department of Anesthesia except for occasional lectures by distinguished leaders in medicine whose special field of endeavor has definite bearing on anesthesiology. The avowed goal, prior to the first course, was thorough indoctrination in the basic sciences and in clinical anesthesiology, but the technic of presentation required a willingness to experiment and attempt new teaching technics. The well established approach to teaching one science after another in rotation with appropriate text assignments was abandoned as unsatisfactory in principle for postgraduate students. The possibility of enlisting the assistance of the preclinical faculty was seriously considered and unsuccessfully tried. It is the firm conviction here that the teaching of fundamental sciences to anesthesiologists is appropriately the sphere of the Department of Anesthesia, since the teachers are competent to sort material properly and are able to avoid the morass of a maze of details which, important to the scientist, need application to clinical anesthesiology. The burden in man-hours for the clinical faculty is greatly increased but well worth accepting as judged by the student development in accord with the best tenets of anesthesia.

BASIC CONCEPTS

The philosophy of teaching this course is based on the assumption that postgraduate students are mature persons and desire primarily to learn anesthesiology. For that reason textbook assignments are not made, but material of importance in the form of review articles and current scientific papers which pertain to the subject under consideration is suggested. It was most interesting to discover how frequently and effectively students became familiar with this type of study.

The actual teaching program includes lectures, laboratory exercises, seminars, demonstrations, a thesis and all the other accepted pedagogic methods, but the organization of instruction is a new departure here. Clinical lectures and discussions occupy approximately half the course and are deliberately interspersed with the related basic sciences. For example, the subject of pulmonary pathology is juxtaposed in time to a clinical consideration of atelectasis. The breaking down of what, in the final analysis, are artificial boundaries between fundamental sciences and the clinic is completed in this manner. The student quickly grasps this concept and realizes early and adequately that he is learning material which has definite application in his thinking and his work rather than simply a necessity for the passing of board or other examinations. Not only is his appreciation of scientific material enhanced, but he is taught in this manner to apply the information and the habits of thought of the scientist to his clinical problems. More concisely stated, anesthesiology is presented as an integrated discipline in which the basic sciences are really embraced and not merely worshipped in the far and traditional distance.

It is perhaps necessary to illustrate in greater detail the precise manner in which the material is presented, because of its differences from orthodox pedagogy and for the possible interest of others responsible for teaching programs in anesthesiology.

The first week is devoted to a serious effort to gain the students' interest and is the reason for introducing the dramatic elements in anesthesia practice at the outset. The subjects of hemorrhage, sudden death in the operating room, delirium and the problems of the aged are dealt with in clinical fashion and are illustrated by a large number of actual patient problems and anesthetic records pertinent to the discussion. The form of teaching these subjects is panel in type, with all members of the faculty as participants. This type of presentation in the introductory week has achieved its purpose in setting the tone for the remainder of the course.

The second week is concerned with the theories of narcosis, the fundamentals of simple inhalation technics, the anatomy of the respiratory tract, the signs of anesthesia, and instruction in the proper use of the medical library.

The third week develops this material in that physiologic and biochemical concepts of respiration are presented together with clinical disturbances related to respiration, such as hypoxia and cyanosis. The clinic is further emphasized in the consideration of resuscitative procedures. Thus anatomic, physiologic and chemical facets of respiration are woven together on the clinical loom.

The fourth week completes the pulmonary material in consideration of special respiratory problems of obstruction and serves to introduce the discussion of the endotracheal catheter as an airway. This period introduces the guest lecturer. The week is rounded out by the presentation of several classic papers in the literature with biographic sketches of the authors.

The fifth week is concerned with the teaching of spinal and epidural anesthesia, its clinical aspects being freely coordinated with the pertinent neuroanatomy and neurophysiology.

The sixth week is largely devoted to metabolic considerations, including the applications which disturbed metabolism have to anesthesiology. A day of physical chemistry in which the gas laws are delineated completes the week

The physiology of the circulation is considered in the seventh week and is discussed in connection with disturbances in cardiovascular activity which may occur during operation or as the result of the action of anesthetic drugs. Special cases are also considered in detail. The management of refrigeration, patients with diaphragmatic hernia and barbiturate intoxication is included.

This philosophy is followed throughout the twenty-four weeks of the course, and the organization of subjects is maintained in similar fashion until the entire scope of the specialty and its related sciences has bee considered. Student initiative is encouraged in second half of the course in the form of student pl and executed seminars and the writing of a the

are given 16 hours, physiology 14 hours and cadaver dissection 30 hours. Some 15 hours are devoted to seminars and reviews, which are conducted by the students and the entire anesthesia faculty as a joint enterprise. Occasional informal hours are planned for question periods, discussions on economics and other projects. These usually total 4 hours. Approximately 150 hours are devoted to the clinical aspects of the specialty.

Although this course was planned as a postgraduate exercise, experience with it has been such as to consider it a necessity for the residents in addition to its first conceived function. The admixture of postgraduate students and residents in a single course has been a profitable one for both groups and the university faculty.

Thus far this discussion has been confined largely to the urgent problem of training anesthesiologists *de novo,* but instructional demands on teaching institutions extend to the postgraduate level, which, in effect, is equivalent to satisfying the educational needs of physicians who are already practicing the specialty. All of medicine is fluid, and newer advances require periodic opportunities for reorientation, the appreciation of changing points of view of the leaders in the various fields of medicine and exposure to improved scientific and clinical developments. Short courses in various aspects of anesthesia of several weeks' duration are adequate if specialists are encouraged to participate enthusiastically as teachers and students, depending on their interests and qualifications.

An example of such a course here is one in regional anesthesia. It is intensive and is given for three weeks semiannually. Included are cadaver dissection, practical instruction on patients in nerve block procedures and complete didactic coverage of diagnostic and therapeutic nerve block. This course is designed for anesthesiologists and others who desire special training in regional procedures. In this course also the discussion and lecture material is closely correlated with the dissection and is applied directly to appropriate patients.

At the present time the postgraduate division of the Department of Anesthesia has had experience covering two academic years. The impression has not been gained that the ideal in graduate or postgraduate education has now been achieved. Improvement and change will always be incorporated in the attitudes of the faculty, and educational errors, when found, will be eliminated. The types of training and teaching that have been outlined are most encouraging in achieving the ends desired—a group of physicians who have learned to look on anesthesiology as a highly developed clinical art which rests on a firm scientific foundation, the constituents of which they are able to evaluate critically and to which they can perhaps even furnish contributions of value.

The attitudes toward the education of anesthesiologists presented in this discussion are based on the advantages afforded by medical schools which are iented sympathetically toward the development of the ialty. It is in institutions of the university classifi n that adequate library possibilities, abundant al material, opportunity for laboratory experience academic atmosphere may be collected for the of the student. It is the obligation of these ons to provide graduate education in anes gy.

PROGRAM FOR THE ACTIVATION OF NEUROLOGY UNDER THE VETERANS ADMINISTRATION

PEARCE BAILEY, M.D.
Washington, D. C.

A year ago Percival Bailey[1] in his chairman's address to this section presented factual data to demonstrate the present ills of neurologic practice and recommended, among other things, that neurologists leave most of the practice of psychiatry to psychiatrists and that neurology become more closely alined with its related basic sciences and with neurosurgery. Whatever the prevailing opinion might be concerning the feasibility of a separation of neurology from psychiatry (at least for the time being), it is evident that Dr. Bailey's paper portrays objectively the present critical state of clinical neurology and may well serve as the landmark for a renaissance in the practice of neurology by neurologists.

Two questions come immediately to mind in evaluating the present status of and the future outlook for clinical neurology, namely: 1. Is there an actual need for clinical neurologists in the diagnosis and treatment of nervous and mental diseases? 2. If such an actual need exists, are neurologists as a group prepared to formulate and back a positive program in order to induce more bright young men to join their ranks?

We are not qualified to state the need for clinical neurologists in civilian practice. This has been emphasized by others.[2] However, we do know something about this need in the Neuropsychiatry Division of the Veterans Administration. Among the most persistent appeals coming into Washington from Veterans Administration hospitals and clinics are requests for the services of qualified neurologists. Nine times out of ten the reply must be "Regret, but no neurologist available for that area nor is there any prospect of finding one in the immediate future." The demand for qualified neurologists in the Veterans Administration is large, and at present we can only partially meet it, even after tapping all available outside sources. Perhaps the thousands of veterans with neurologic disabilities arising from two world wars will play some part in the shaping of the future of clinical neurology!

It is estimated that at least one third of the neuropsychiatric patients in general hospitals of the Veterans Administration are neurologic cases. About 50,000 epileptic veterans will require study and treatment in the next ten years. Among the casualties of World War II there are about 20,000 craniocerebral injuries, almost 3,000 paraplegics and 600 post-traumatic aphasic patients. Neurologic residuals from acute infections were proportionately far greater in World War II than in World War I, since chemotherapy and improved methods of care saved the lives of many men who with similar diseases died in World War I. As time goes on and veterans become older and hence more vulnerable to neurologic insults the number will steadily increase. For example, the peak of the neurologic census from World War I is not expected to be reached until 1949.

Read before the Section on Nervous and Mental Diseases at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1947.

[1] Bailey, Percival: The Practice of Neurology in the United States of America, J. A. Am. M. Coll. **21:** 281, 1946.

[2] Wilson, G., and Rupp, C.: Present Trends in the Practice of Neurology, J. A. M. A. **133:** 509 (Sept. 22) 1947. Bailey.[1]

A hint of what may be expected in the way of an increasing census of diseases of the nervous system is observed by a glance at the incidence of neurosyphilis. During the fiscal year of 1945, 2,556 veterans were treated in hospitals for symptomatic neurosyphilis. Of this number only 233 were veterans of World War II, the remainder, or 2,323, being veterans of previous wars. Now the question is naturally posed as to how many veterans of World War II will eventually develop neurosyphilis. At present this cannot be very accurately estimated, since the long-term results of the newer treatment methods for syphilis are not known. The Subcommittee on Venereal Disease of the National Research Council has estimated that approximately 12,500 veterans will develop symptomatic neurosyphilis over a spread of twenty-five years. This estimate is considered to be minimum, since it was made before it was known that variation had occurred in the potency of commercial penicillins.

To give these veterans with neurologic disorders the kind of medical study and treatment to which they are entitled by law and to develop this unique opportunity for follow-up studies on the largest group of neurologic patients ever to be assembled, so to speak, under a single roof, an ambitious program in neurology has been promulgated by the Veterans Administration which transcends strict intramural bounds by dedicating itself to the task of stimulating an increased interest in the general field of neurology wherever there is a hope to find a worthy response. Today there are not enough qualified neurologists in the country with sufficient time at their disposal to provide the desired type of care, and, unless more young men of high caliber can be attracted to neurology, the future care of veteran neurologic patients will be placed at a distinct disadvantage.

Our program, briefly, consists of two parts. The first aims at the development of existing facilities in neurology to the highest possible professional level with the materials that are now available. The second is designed to attract young physicians to the discipline of neurology in order to keep in step with expanding needs. Both parts of the program are now in active operation, but the former is naturally more advanced than the latter.

Let us consider the first part of the program in the light of its objectives and the work that has been accomplished during the first ye[illegible] This may be summarized under six [illegible]: (1) decentralization of responsibility to the various branch areas of the Veterans Administration, (2) recruitment of qualified neurologists, (3) establishment of neurologic centers, (4) organization of residency training programs in neurology, (5) organization of specialized professional courses for neurologists and ancillary personnel and (6) promulgation of a sound program in research.

DECENTRALIZATION

In line with the overall policy of the Veterans Administration, considerable authority and responsibility for neurologic activities has been decentralized to the various branch offices in order to expedite activity. There are thirteen of these branches throughout the country, and the relationship of each branch to the central office in Washington is somewhat analogous to the relationship of state government to federal government in a jeffersonian democracy.

RECRUITMENT

Early in the task of reorganization of neurology in the Veterans Administration it became apparent that an outstanding deficit was the lack of qualified personnel to handle the new and staggering load of patients. Accordingly, branch section chiefs in neurology were appointed to supervise the activities in their respective areas. These section chiefs are all men of professorial rank in neurology and are members of the American Neurological Association. Moreover, the services of an additional 100 qualified neurologists were obtained, many of them members of the American Neurological Association, to act as full time and part time physicians and as attending physicians and consultants to hospitals and clinics. These men supply a nucleus for future growth.

NEUROLOGIC CENTERS

Seven neurologic centers have been established in general medical and surgical hospitals of the Veterans Administration, and additional ones are under development. These centers serve as diagnostic and treatment units to which patients from less adequately equipped hospitals and field stations may be referred. Certain national projects for the rehabilitation of large groups of veterans with similar neurologic disabilities, such as the paraplegics and the post-traumatic epileptics and aphasics, are being carried out in these centers.

RESIDENCY TRAINING

Eight residency training programs which provide for three years of training in basic and clinical neurology, including six months in psychiatry, are now under way. These residencies are under the direction of the neurologic departments of medical schools as prescribed by the dean's committee plan of the Veterans Administration. According to the plan, residents spend half their time in the Veterans Administration neurologic center and the remaining half in the lecture rooms, laboratories and hospitals of the medical school. The type of training received by these residents probably compares favorably with that of neurologic institutes. Moreover, in many instances the Veterans Administration residents have the benefit of contacting a greater variety of clinical material. Thus, for example, in one hospital with a residency training program there are 300 paraplegic patients in addition to 225 beds allocated for a neurologic diagnostic service.

PROFESSIONAL COURSES

It has been necessary to organize professional courses in specialized fields which are relatively young and have not as yet set up uniform standards of skill or performance, as for example electroencephalography. To date 35 physicians and technicians have been trained in electroencephalography under Dr. Frederic A. Gibbs at the University of Illinois, and of course we intend to train many more. As the Veterans Administration electro- [illegible] laboratories build up, this program [illegible] to the branches. Other profession[illegible] courses now in operation provide for the training [illegible] personnel in the rehabilitation of aphasic patient[illegible] for the instruction of nurses in neurologic and [illegible] surgical nursing.

RESEARCH

No medical program can be long maintained [illegible] gear without the benefit of the stimulus provid research. This has particular reference to the pr

ases of a
to account
adequately
this anti-
reported in
New York.

of the Veterans Administration, where enthusiasm is apt to lag as the exhilaration provided by the war diminishes. Moreover, the vast amount of clinical material now available for medical follow-up studies supplies an impelling reason to use this unique occasion to advance our knowledge of injury and disease. Much time and thought have been given to this problem, but the organization of research projects in the Veterans Administration is necessarily slow. However, a national research project in epilepsy under the supervision of Dr. William G. Lennox has been started at the Cushing Veterans Hospital near Boston. Additional projects are pending.

The essence of the second part of our program is to attract, either directly or indirectly, more keen young men to the discipline of neurology in order that the Veterans Administration will be in position to draw its neurologists from a larger pool of talent than that which exists today. A veil of confusion envelops the entire subject of neurology. Prospective neurologists sense this confusion and are discouraged by what are construed to be practical disadvantages for one contemplating a career in clinical neurology. One naturally hesitates to cast one's lot with what has been termed by some as "a dying race," even though it may not be supported in fact. The confusion surrounding the status of neurology must be cleared and the practical disadvantages confronting prospective neurologists must be ameliorated before hopes of acquiring much new talent can be validly entertained.

From a survey of the literature and from our experiences in recruitment of neurologists we have listed what appears to be the major obstacles and sources of confusion facing physicians contemplating a career in neurology. Having accomplished this, we have attempted to fashion our program in such a way that it will absorb as far as possible these impediments and thereby clear the obstacles which apparently are blocking the path of entry for prospective neurologists. We have listed these obstacles and sources of confusion under four headings, namely (1) the neurologist's problem of earning a living, (2) relation of neurology to neurosurgery and the basic sciences, (3) the neurologist's dilemma with regard to therapy and (4) the prevailing psychologic orientation in psychiatry.

THE NEUROLOGIST'S PROBLEM OF EARNING A LIVING

The chief resistance of physicians predominantly interested in neurology to enter the field of neurology is a fear of not being able to "make a decent living" from an exclusively neurologic practice. The basis of this fear appears to lie in the fact that the clinical neurologist in private practice can no longer count on deriving a substantial portion of his income from treating the psychoneuroses to compensate for the frequent dearth of neurologic patients. Psychoneurotic patients have largely passed to the psychologically oriented psychiatrist, who may be better equipped both temperamentally and experientially for an understanding of this type of patient.

The Veterans Administration, by offering residency ing and full time and part time positions to neurolo- and prospective neurologists has diminished this ic hazard. Qualified neurologists may secure positions with respectable pay and may devote time to clinical neurology or its related basic r they may hold part time positions as attend- cians or consultants and receive up to $6,000 a year for this work, which would help to compensate for the paucity of neurologic patients in private practice.

Thus, for example, a doctor may begin his career in an approved residency alined with the teaching program of a medical school, with pay at least equal to any corresponding civilian residency. After completion of his three years of training he may obtain a full time position with valid remuneration in the neurologic service of a Veterans Administration hospital until the time he is eligible for certification as a specialist. During this period he may have the opportunity without expense to add to his psychiatric training or to take up surgery or to increase the scope of his professional skill by taking a training course in electroencephalography or by joining some special research project, as for example the one in epilepsy. On certification, the young physician may continue in a higher grade on a full time basis with the Veterans Administration or he may enter civilian practice and be eligible for appointment as an attending physician to a Veterans Administration hospital or clinic, for which service he could receive up to $6,000 a year. It is hard to conceive of a plan that would offer more security to a young doctor during the trying years of basic training and beyond.

RELATION OF NEUROLOGY TO NEUROSURGERY AND THE BASIC SCIENCES

Another nebula clouding the perspective of the future neurologist is what Walshe and Symonds[3] describe as "the nettle of future relationships of neurology to neurosurgery." The basic question is Where does neurology end and neurosurgery begin, and vice versa? It is likely that this problem can be resolved only by a closer entente between the neurologist and the neurosurgeon, both of whom should implement and complement the other. With the collaboration of Dr. R. Glen Spurling, director of neurosurgery in the Veterans Administration, a closer integration between the two specialties is being sought by combining them, wherever practicable, into a single unit of activity.

Therefore, what has been termed so far as neurologic units are actually, as far as possible, neurologic-neurosurgical units. All patients, except acute surgical emergencies, are admitted to the neurologic service for initial study and work-up. Subsequent transfers of surgical cases are made to the neurosurgical service after consultation with the neurosurgeon. On completion of the necessary procedures, patients are returned to the neurologic service for convalescent care. Neurosurgeons have access to the neurologic part of the unit to increase their knowledge of neurologic disease, whereas neurologists have similar privileges on the surgical side of the unit in order that they may gain a closer understanding of neurologic surgery.

Few would resist the plea of Percival Bailey[1] for a closer union between clinical neurology and its related basic sciences. He remarks "Neurophysiology in this country is making rapid advances which are just crying to be applied in the clinic" and later adds "There are innumerable unsolved problems in clinical neurology awaiting the investigator who comes into the field through some basic discipline which can apply to them." Indeed, one of the difficulties we encounter in the recruiting of neurologists is this very lack of coordination between laboratory and clinic.

[3] Walshe, F. M. R., and Symonds, C. P.: Neurologist and Neurosurgeon, Brit. M. J. 2: 364 (Sept. 15) 1945.

The Veterans Administration has taken cognizance of the need of a closer liaison between laboratory and clinic. By means of the dean's committee plan, some of our neurologic services have been brought into close contact with the laboratories of medical schools. But only a few medical schools provide adequate laboratory facilities for the investigation of all aspects of neurologic problems. Therefore we have included in our program provisions for the establishment of additional laboratories. This, however, has not as yet progressed beyond the planning stage.

THE NEUROLOGIST'S DILEMMA WITH REGARD TO THERAPY

The traditional garb of the neurologist is that of a diagnostician *par excellence* with little interest in therapy. Cloaked in this manner he has been forced to witness many cases which were entrusted to his care taken over by others because their treatment had been initiated elsewhere. Riley[4] sounded a knell of warning as to what might be expected as the result of the neurologists' indifference to therapy, but little has been done about it. Probably a great source of discouragement to physicians entertaining the possibility of becoming neurologists is the lack of a therapeutic orientation in neurology—particularly in this age, which is unmistakably therapeutically minded. In addition, it gives rise to the paradox that those who understand the structural implications of a disease best are not entrusted with its care—a phenomenon which is not in consonance with the optimal interests of the patient.

In the Veterans Administration the primary medical objective is and must be therapy. It is our duty to assess the mental and physical assets of each patient and develop them to the maximum in order that he will be less of a burden to himself, to his family and to the government. This strong therapeutic orientation should help solve the neurologist's dilemma about therapy. Our residents will be thoroughly trained in all methods of treatment of neurologic disorders, and it is expected that they will continue to apply the results of this experience after completion of training.

To cite an example of the therapeutic bent of the Veterans Administration would be timely. About eight months ago the Neurologic Service of the Veterans Administration Hospital at Minneapolis, which is under the supervision of Dr. A. B. Baker and Dr. Joe Brown, inherited 73 patients, all veterans of World War I. These patients were all bedridden; some had been in bed for over ten years—they belonged to that class of neglected men known as chronic neurologic patients. They were a heterogeneous group composed of cases of parkinsonism, multiple sclerosis, cerebellar atrophies, tabes dorsalis and vascular disease.

The chiefs of this service organized a "total push" program of therapy. In collaboration with the Medical Rehabilitation Division and its ancillary services and utilizing methods of muscle reeducation, physical therapy, prosthetic devices and psychologic motivation technics they began their job to rehabilitate these patients. The results more than justified the effort involved. Within eight months all but 6 of the original 73 patients were out of bed. Thirty-one patients have been discharged to their homes; 8 of this number are capable of self support and the remaining 23 are able to do some work. An additional 15 have achieved self care. Twenty-one more are up and about, enthusiastically working on their rehabilitation, and have a good outlook for the future. It is believed that by the use of these therapeutic methods about 75 per cent of chronic neurologic veterans can be placed on a level of self care, which means greater happiness which is their due, and an enormous saving to the government.

It is true that this form of therapeutic attack may lack the drama and sensationalism associated with some of the more rapid forms of medical therapy, but it supplies a wedge by means of which our neurologists can actively push further into the general treatment field with the ultimate goal of assuming responsibility of the treatment of all diseases which belong in their bailiwick. It is only in this way that veterans with neurologic disease can be assured the highest level of medical care from time of diagnosis to time of disposition.

THE PREVAILING PSYCHOLOGIC ORIENTATION IN PSYCHIATRY

Another distraction to the budding neurologist is the dramatic rise of the psychologic approach to the study of mental and emotional disorders. This methodology, which has been too long neglected in medicine, has risen to the fore and now occupies the driver's seat in psychiatry. Concerned on the one hand with the needs of the individual as a total person, particularly in terms of the dynamics of his psychosexual development and interpersonal contacts, and on the other hand entering the domain of anthropology and social psychology, as it applies to the betterment of existing social ills, "dynamic psychiatry" has a tremendous scope which encompasses the entire field of human relationships. This gives a compelling gregarious and literary appeal to the purely psychologic aspects of psychiatry. There is little question that the present lure of the prevailing psychologic orientation in psychiatry has diverted some young physicians from devoting much time to the study of neurology.

In spite if the enormous contribution of the psychologic approach to the effectiveness and growth of psychiatry, the irrefutable argument for further progress in neurology as an aid both to itself and to psychiatry is the fact that nearly all stimulus impulses and experiences are integrated and elaborated into higher reaction patterns through the mediation of the nervous system. Hence, in order to develop an ever increasing knowledge of neuronal activity and of the meaning of human behavior in terms of underlying physiologic mechanism, it is necessary to continue to increase our grasp of the functions and structure of the nervous system. At the present time this can be accomplished only on a proper scale by an activation and integration of the entire field of neurology.

The only persons to stimulate a renaissance in neurology and to convey its meaning to the rising generation of physicians are neurologists. But neurologists are noted for a certain aloofness to pushing or maintaining their cause, and for their conservatism. Would it nc
be better to modify this attitude somewhat, particular
in view of the present day aggressive trends in alm
all medical specialties? Should not the traditional
servation be relaxed to some degree? Would it n
better for neurologists to unite in a spirit of con
tive affirmativeness to formulate a program
activation of clinical neurology? I am convin
the future care of many neurologic veteran
hinges in no small degree on the answers
questions.

[4] Riley, H. A.: Training of the Neurologist: Neurologia Irredenta, Arch. Neurol. & Psychiat. 29:862 (April) 1933.

ABSTRACT OF DISCUSSION

DR. J. M. NIELSEN, Los Angeles: Dr. Bailey has pictured in detail the dilemma of neurology. The two fundamental causes of the situation are that the neurologist has not sufficiently expanded his interests to help out other specialists on borderline cases and that the neurologist will of necessity have to diagnose and treat psychoneuroses, for which purpose he needs considerable knowledge of psychiatry. I should like to limit the discussion now to the means by which the neurologist lives, for if he does not live he cannot serve his specialty regardless of how well he is prepared. The neurologist serves the general practitioner as a diagnostician and as a means of placing therapy on a sound basis. He serves the otolaryngologist and the ophthalmologist in distinguishing when a disease at first limited to one region of the body invades the brain. He serves the orthopedist in differential diagnosis of painful conditions and in diseases of the muscles. He serves the general surgeon in differentiating functional abdominal states from surgical ones. The anesthetist refers cases when complications arise. The obstetrician refers both mother and baby for trauma at birth. The urologist asks for help on suspected neurogenic bladder, the radiologist for interpretation of etiology of roentgenologic conditions. Even the psychologist and the electroencephalographer ask for help. Last but not least, the Industrial Accident Commission constantly needs help in a neurologic survey of traumatic cases. If the young neurologist will make himself capable of rendering genuine help in these fields, he will have no difficulty making a living.

CARCINOMA OF THE LARGE INTESTINE

Diagnostic Errors in Relation to Location of the Lesion

RAYMOND J. JACKMAN, M.D.
HAROLD A. NEIBLING, M.D.
and
JOHN M. WAUGH, M.D.
Rochester, Minn.

In spite of the existence of accurate diagnostic procedures and intensive educational campaigns directed toward both physician and patient, many carcinomas of the large intestine become far advanced before a diagnosis is made. In 1924, after reviewing the records of 1,937 patients who had carcinoma of the rectum or sigmoid, Buie[1] made the statement that 1 of every 5 of these patients had been operated on for hemorrhoids or had been treated symptomatically for some type of organic disease, other than the carcinoma. The aforementioned author has made this statement repeatedly since that time. It is remarkable, however, that during the period of their symptoms just as many patients as heretofore continue to receive treatment for some supposed condition of the rectum or colon other than the carcinoma, which thus remains undiscovered.

The purpose of our study was to determine the nature of the treatment in relation to the location of the carcinoma. More specifically, the study consisted in considerations on (1) how many carcinomas of the large intestine within reach of the examining finger are diagnosed and treated as some other disease during the course of the patient's symptoms, the carcinoma remaining undiscovered; (2) how many additional carcinomas which should have been visible at sigmoidoscopic examination are erroneously treated, and the nature of the treatment; (3) how many carcinomas discernible in roentgenograms of the colon likewise are erroneously treated, and the nature of the treatment, and (4) how many carcinomas of the large intestine are discovered only at surgical abdominal exploration.

To answer these questions we studied the records of all patients with carcinoma of the colon and rectum who came to the Mayo Clinic during a one year period; that is from Jan. 1, 1944 to Jan. 1, 1945. There were 817 patients in the group with a total of 825 lesions; 492 of the patients were men and 325 were women, a ratio of 3:2. The situations of the lesions are represented in the accompanying illustration.

LESIONS ACCESSIBLE TO THE EXAMINING FINGER

It should be emphasized that although we have divided the 817 patients into four groups, according to the method of diagnosis employed, the diagnostic procedures overlap. That is, the use of one diagnostic procedure frequently calls for the use of another as a supplementary or confirmatory aid. For instance, a rectal carcinoma, although palpable, should be examined with the proctoscope to gain additional information, such as the degree of obstruction, the situation of the lesion and whether or not polyps are associated, and to permit removal of a specimen for biopsy. Similarly, if a polyp or bloody mucus is visualized with the proctoscope, roentgenologic study of the colon is indicated.

Whether or not a carcinoma of the lower part of the bowel is palpable on digital examination is dependent on several factors: (1) the situation of the lesion; (2) the position of the patient at the time of examination; (3) the degree of obesity and muscular development of the patient; (4) the ability of the patient to cooperate; (5) the thoroughness of the examiner, and (6) the mobility of the lesion.

Of the entire group of 817 patients in this study, 634, or 77.6 per cent, had carcinomas which were located in the terminal portion of the bowel, meaning the sigmoid, rectum and anorectal region. The lesions of 444 patients (70 per cent of the 634 who had lesions of the terminal part of the bowel or 54.3 per cent of all those who had carcinomas of the large intestine) were palpable on digital examination or were within reach of the examining finger. Many of the lesions of the sigmoid were palpable in the form of extrarectal masses, and actually were suspected rather than being directly palpable. Nine of the 444 patients who had lesions within reach of the examining finger had to be examined under the influence of caudal sacral anesthesia because of their inability to cooperate or because the lesion had extended to involve the sensitive anal area.

Of the 444 patients, who had palpable lesions, 102, or 23 per cent, had received treatment during the course of their symptoms other than therapeutic measures directed toward the unsuspected carcinoma that later was found to be within reach of the examining finger. Analysis of some of the various therapeutic procedures instituted in this group of 102 patients showed that 42 underwent surgical treatment for hemorrhoids, and that 4 of these patients were subjected to this procedure twice. Another group of 35 patients received a form of injection treatment for hemorrhoids. Four patients underwent surgical treatment of fissure; 4 underwent fistulectomy; 4 others underwent some form of anorectal surgical procedure, the exact nature of which the patient did not know. Three patients were treated for colitis and 3 for amebiasis. Another 4 patients received electrical treat-

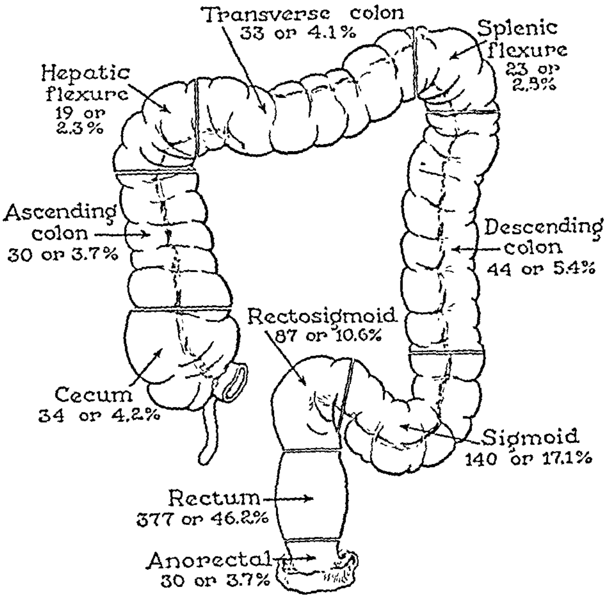
ment for hemorrhoids; 3 others were treated with suppositories. Interesting is the fact that, as previously mentioned, each of 4 patients underwent two operations for hemorrhoids while they had the symptoms of carcinoma.

LESIONS NOT ACCESSIBLE TO THE EXAMINING FINGER BUT VISIBLE AT PROCTOSIGMOIDOSCOPY

As stated previously, proctoscopic or sigmoidoscopic examination is not a substitute for digital examination, just as digital examination is not a substitute for that with the proctoscope. Information of a somewhat different nature is obtained by each method. In proctoscopic examination the surgeon is interested in determining several things, such as, first, the situation and extent of the lesion in relation to the number of centimeters of normal bowel distal to it, so that he may obtain necessary information as to the type of operative procedure advisable. Next, he wishes to ascertain the degree of obstruction, since this knowledge is important from the point of view of preparation of the patient. Third, he wishes to secure a specimen of tissue for biopsy, so that the grade of the lesion can be determined. Fourth, he seeks to learn the degree of mobility or fixation of the lesion, since this is important from the point of view of operability. This factor, however, finally must be determined at the time of surgical exploration.



Situation of the carcinomas of the large intestine of 817 patients, according to number of patients, percentage and site of occurrence within the designated structure or region. (There were 8 patients with multiple lesions.)

In addition to the 444 patients (54.3 per cent of all those who had carcinomas of the large intestine) who had lesions palpable on digital examination, all of which were visualized at proctosigmoidoscopic examination, 132 additional patients, or 16.2 per cent, had lesions of the lower bowel which were visible by sigmoidoscopic study. Thus a total of 576 patients (70.5 per cent of the total series of 817) had carcinomas of the large intestine which were within reach of the sigmoidoscope.

In this group of 132 patients with lesions which were not palpable on digital examination but were within reach of the sigmoidoscope, 34, or 25.8 per cent, had received treatment directed at some disease process other than the carcinoma, which had remained undiscovered. An analysis of this group of 34 patients showed that 28 patients had been treated either surgically or by some unknown procedure involving the anus. One had undergone fistulectomy, 3 had been treated for amebiasis and 2 had been treated for ulcerative colitis. Parenthetically, it might well be pointed out that amebiasis, like chronic ulcerative colitis, can coexist with carcinoma of the large intestine.

LESIONS DISCERNIBLE IN ROENTGENOGRAMS OF THE COLON

Of the patients who had lesions located higher in the colon, beyond the reach of the examining finger and the sigmoidoscope, 232 (28.4 per cent of the total series of 817) had carcinomas which were diagnosed by roentgenograms of the colon. Twenty-three patients, or 9.9 per cent, of this group had received other treatment during the period in which they were experiencing symptoms due to the carcinoma. Six had been operated on for hemorrhoids. Five had been treated for pernicious anemia by the intramuscular injection of liver extract. It is generally accepted that a secondary type of anemia is of common occurrence in the presence of malignant processes of the right portion of the colon. Five patients had been treated for colitis of some form; 2 had been treated for amebiasis and 2 had undergone appendectomy. In the last 2 cases the carcinoma had remained undiscovered, even though it was located in the cecal region. Polyps in the rectum had been diagnosed and treated in 3 patients, but carcinomas situated in a higher segment of the colon had not been discovered. It should be pointed out that the discovery of one polyp or more in the lower bowel ought to be an indication for examination of the rest of the colon by roentgen rays, with which the double contrast method is employed.

LESIONS ENCOUNTERED AT SURGICAL ABDOMINAL EXPLORATION

The remaining 9 (1.1 per cent of the total series of 817) of the 817 patients had lesions that had been diagnosed only at surgical abdominal exploration. In most instances in this group performance of emergency colostomy had been necessary because of obstruction of the large bowel, and the diagnosis had been made at the time of that operation. No significant treatment had been carried out for members of this group during the period in which they had experienced symptoms from carcinoma.

COMMENT

Paradoxic as it may seem, results of this study indicate that those patients who have carcinomas of the large intestine which can be diagnosed with the greatest ease—that is, by digital examination only—are more likely to be treated for some condition unrelated to the carcinoma. Of the 444 patients, or 54.3 per cent of the total of 817, who had lesions palpable on digital examination of the rectum, 102 (23 per cent of the 444), or 1 of every 4, had received some other treatment not directed at the carcinoma during the period in which they were experiencing symptoms from the unsuspected carcinoma. In comparison to this, of the 232 patients who had lesions located at a higher level in the large intestine 23, or 9.9 per cent of the 232, had been treated for some other disease, while none of the 13 patients who had carcinomas diagnosed at surgical abdominal exploration had received treatment for the lesion in question.

SUMMARY AND CONCLUSION

In the group studied, more than half (54.3 per cent) of all patients with carcinoma in any part of the large intestine had lesions which could be palpated by digital examination of the rectum. About a fourth (23 per cent) of the patients in this group had received some form of treatment for disease of the colon or rectum, but not for carcinoma, during the course of their symptoms arising from the unsuspected carcinoma that was within reach of the examining finger.

An additional 16.2 per cent of all the patients who had carcinomas anywhere in the large intestine had lesions which were within reach of the sigmoidoscope. A fourth (25.8 per cent) of this group had received treatment for some disease other than the carcinoma, which had remained undiscovered.

Patients who had carcinomas of the large intestine that were beyond the reach of the examining finger and sigmoidoscope constituted the remaining 29.5 per cent of the total series of 817. Of this group, 28.4 per cent had carcinomas that were diagnosed by roentgenologic studies of the colon, and 1.1 per cent had lesions that were discovered at abdominal surgical exploration. In this group, during the period of symptoms from carcinoma, only 9.9 per cent of the patients had received treatment directed toward any other condition.

CLINICAL EVALUATION OF VASCULAR DAMAGE IN DIABETES MELLITUS

HENRY DOLGER, M.D.
New York

The discovery of insulin twenty-five years ago served to avert the catastrophic threat to life represented by diabetes mellitus but unfortunately initiated an attitude of complacency in the members of the medical profession. What was intended as a palliative became the panacea; control of the blood sugar level was interpreted as control of the disease. But "maintenance of life is not sufficient in itself as a goal in the treatment of diabetes mellitus."[1] The optimism of that early period is now being dissipated by a number of anxious reports[2] on the mounting incidence of seemingly inevitable degenerative sequelae. Rosenbusch[3] has concluded a painstakingly thorough study of 88 diabetic children with the following: "The prognosis of diabetes in childhood—taking a long view—is in spite of the progress of dietary and insulin treatment more adverse than had originally been expected." Joslin[4] has found evidence of vascular damage in 70 per cent of 250 juvenile patients despite twenty years of treatment. Wagener's[5] most recent survey from the Mayo Clinic recognizes the seriousness of "the steadily increasing frequency of retinopathy, especially in the younger age groups."

A unique association of diabetes with vascular damage in various organs was described as a pathologic and clinical entity by Kimmelstiel and Wilson[6] and termed "intercapillary glomerulosclerosis." Subsequent reports[7] have stressed the terminal nature of this syndrome, with its clinical aspect limited to the triad of hypertension, retinopathy and albuminuria. Failure to study the pathogenesis of this condition stands in decided contrast to the pathologist's zeal in ferreting out the characteristic glomerular lesion with increasing[8] frequency among diabetic persons. It is the purpose of this paper to demonstrate that this syndrome exists with varying expressions of severity in every instance of diabetes mellitus of some duration.

MATERIAL

Two hundred patients in whom the onset of diabetes occurred before the age of 50, either in childhood, adolescence or adulthood, were the subjects of this study. Fifty-five were juvenile patients in whom the diabetic condition began before the age of 20. These patients formed a special group, which will be discussed in greater detail than the others. The infrequency of significant vascular damage in nondiabetic persons of this age obviated the need for a comparison group. The patients were selected from the metabolism clinic of Mount Sinai Hospital and private practice on the basis of detailed medical records dating from the onset of diabetes, with emphasis on regular ophthalmoscopic examinations, determinations of blood pressure and complete urinalyses. These procedures were performed on each visit to the physician, month after month and year after year, so that a picture of the evolution of abnormal observations was obtained. Consequently the results are not comparable with those of many investigations[9] based on single or "spot analyses" of similar patients. No mydriatics were used for ophthalmoscopy; careful scrutiny of the retina through the undilated pupil proved surprisingly successful and permitted unprotested repetition of this examination on each visit. "The earliest and the most characteristically diagnostic and therefore possibly the basic lesion is the small punctate hemorrhage in the presence of ophthalmoscopically normal retinal vessels."[5] Elevation of the diastolic blood pressure above 90 mm. of mercury was considered evidence of hypertension in the case of juvenile patients; for adults 100 mm. was taken as the critical reading. Albuminuria was so constantly associated with cylindruria that the former term will be used in this inclusive sense throughout the paper.

DIABETIC CONTROL

The 55 juvenile patients included 19 whose diabetes began before the tenth year. (One patient in this group had had diabetes since the age of 11 months.) There have been 7 fatalities among the 55; 3 with intercapillary glomerulosclerosis, 2 cerebral accidents without hypertension and 2 postoperatively of unknown causes. These 7 will be the subject of a future report.

The accepted dictum that "control" of glycosuria influences the development of degenerative change served as the basis for the analysis presented in table 1. The treatment of 20 young diabetic patients satisfied all orthodox criteria for excellent diabetic control, namely, adherence to moderate carbohydrate, low fat

diets and exhibition of little or no glycosuria. Within a range of six to twenty-two years' duration, retinal hemorrhages were noted in all, with an average duration of diabetes of thirteen years when the earliest lesions were observed. By the time retinopathy had developed 50 per cent of patients presented definite hypertension and 30 per cent albuminuria. The first patient to receive insulin at Mount Sinai Hospital was a girl 9 years of age. The control of her disease has always been considered perfect. For the past ten years she has never presented a single instance of glycosuria on a diet of carbohydrate 150 Gm., protein 80 Gm. and fat 80 Gm., with a fixed dose of 60 units of protamine zinc insulin. Twenty-two years after the onset of diabetes numerous retinal hemorrhages were observed along with albuminuria and a blood pressure of 150 systolic and 100 diastolic.

A parallel group of 18 patients in whom only a fair degree of diabetic control could be obtained presented retinal hemorrhages within five to twenty years after onset, the average duration of diabetes for the group being 10.4 years. At this time one third of the 18 patients displayed hypertension and albuminuria.

A third group of 17 patients had been categorized as having an unusually severe brittle form of diabetes in which glycosuria and hyperglycemia defied all therapeutic measures. The regimentation of diet evoked such resistance in many of these children and produced such pronounced psychic trauma [10] that *faute de mieux* a free diet was condoned. In recent years these patients were even encouraged to continue this regimen as more and more divergence of opinion appeared on the subject of the ideal diet. Lichtenstein [11] summarized the conflict among the proponents of various dietary manipulations in the following: "If any valid scientific grounds for the superiority of a certain form of diet had existed, this diet would doubtless have soon superseded all the others." The incidence of retinal hemorrhage was noted between five to nineteen years after the onset of diabetes, an average group span of 12.4 years. Hypertension accompanied this finding in 40 per cent of patients and albuminuria in 64 per cent with both usually occurring in the same patients.

TABLE 1.—*Relation of Diabetic Control to Vascular Damage in Fifty-Five Juvenile Patients*

		Onset of Retinal Hemorrhage				
Diabetic Control	No. of Patients	Average Duration of Diabetes, Yrs.	Patients with Hypertension	Patients with Albuminuria	Patients with Vascular Calcification	Patients Subsequently Blind
Excellent	20	13.0	10	6	2	1
Fair	18	10.4	6	7	2	2
Poor	17	12.4	7	11	2	2

The course of the perfectly controlled diabetic girl previously described may be contrasted with that of one of her contemporaries, a boy whose diabetes began in 1926 when he was 4 years of age. He has been on an unrestricted diet for twenty years. When he was but 5 years of age his physician, Dr. A. E. Fischer, admitted that there was "no use pretending to keep this child on a calculated diet." There has been a daily carbohydrate intake of over 400 Gm. plus large quantities of sugar-inducing, continuous glycosuria (60 to 100 Gm.) without a single episode of ketosis in all these years. For the past ten years the dosage of 80 units of protamine zinc insulin has not required alteration. Despite this gross violation of orthodox therapeutic procedure the earliest vascular damage did not appear until nineteen years after the onset of diabetes. At this time several retinal hemorrhages were noted in association with mild albuminuria and a blood pressure of 140 systolic and 100 diastolic. Within almost the same period these 2 patients exemplifying the extremes of diabetic therapy arrived at the same stage of degeneration.

TABLE 2.—*Relation of Age of Onset of Diabetes to Vascular Damage in Two Hundred Patients*

		Onset of Retinal Hemorrhage					
			Patients with Hypertension		Patients with Albuminuria		
Age of Onset of Diabetes	No. of Patients	Average Duration of Diabetes, Yrs.	No.	%	No.	%	Patients Subsequently Blind
0-19	55	13.0	27	49.1	24	43.6	5
20-29	21	13.3	9	42.9	10	47.6	3
30-39	45	13.0	21	46.7	23	51.1	6
40-49	79	10.0	37	46.8	48	60.8	13
Total	200		94		105		27

Table 1 indicates the limitations in the use of the x-ray as a means of estimating early vascular damage. It is noteworthy that when retinal lesions had occurred in 100 per cent of the juvenile patients, and hypertension and albuminuria in 40 per cent, the roentgenologic survey lagged behind with a positive corroboration in only 11 per cent.

SIGNIFICANCE OF AGE

The relation of the age of onset of diabetes to the development of vascular lesions in the entire group of 200 patients is presented in table 2. A remarkable parallelism in observations is evident between the juvenile patients and the young diabetic adults in whom the onset of the disease occurred two decades later, namely, at age 20 to 39. In the group aged 20 to 29 the appearance of retinal hemorrhage was noted between four to twenty-two years after the onset of diabetes, with the average duration for the group of 13.3 years. In the group aged 30 to 39 retinopathy appeared between three to twenty-four years after onset, the average duration of diabetes being thirteen years for the group. The patients of these two decades presented almost identical association of hypertension and albuminuria in about 50 per cent of cases.

TABLE 3.—*The Development of Retinopathy in Relation to the Use of Insulin*

Age of Onset of Diabetes	Treatment	No. of Patients	Aver. Duration of Diabetes at Earliest Retinopathy, Yrs.	Subsequent Progression to Blindness
30-39	Diet alone	12	12.0	3
	Insulin	33	13.5	3
	Total	45	13.0	6
40-49	Diet alone	17	8.3	6
	Insulin	62	10.5	7
	Total	79	10.0	13

The oldest group (onset at 40 to 49 years of age) presented evidence of accelerated vascular degeneration with the earlier appearance of all the abnormal findings with even greater frequency. The retinal lesions were noted between zero to twenty years after the onset of the disease, the average duration being ten years. Several patients showed advanced visual failure even before the classic symptoms of diabetes appeared. The apparent tendency toward the earlier development of retinopathy in the mild (noninsulin) cases (table 3) was due to the inability to estimate the duration of diabetes in cases in which the onset was clinically undramatic. "Duration of the diabetes is a much more important factor than is the age of the patient." [5] The glycosuria of patients in the three older groups was well controlled by insulin and diet or by diet alone.

---

[11] Lichtenstein, A.: Treatment of Children's Diabetes: Ten Years' Experience Without Dietetic Restrictions, Acta pædiat. **32**: 556, 1945.

THE COURSE OF RETINOPATHY

The appearance of retinal hemorrhage often presaged the inevitable pattern of more generalized and progressive vascular degeneration. The rate of progression had no relation to the severity of diabetes or its control. The hemorrhages often resorbed spontaneously, thereby making the effect of any specific therapeutic measures difficult to evaluate. The persistent recurrence of small hemorrhages often escaped notice by the patient or physician because of the lack of appreciable interference with vision. On the other hand, without apparent reason, the sudden appearance of retinal hemorrhages not infrequently progressed to blindness within a year. This disaster occurred when retinitis proliferans developed with subsequent retinal detachment, massive vitreous hemorrhage and secondary glaucoma.

Twenty-seven patients of the total group of 200 became partially or totally blind (table 2). This shocking sequel to retinopathy was found in 5 of the juvenile patients. The duration of diabetes in these cases was fourteen years in 2 instances and sixteen, nineteen and twenty-four years in the others. Table 1 indicates that the control of glycosuria failed to prevent this tragedy. These 5 patients presented the triad of the originally described syndrome of hypertension, albuminuria and nephrotic edema.

OTHER DEGENERATIVE CHANGES

All the blind patients had albuminuria of varying severity; hypertension, however, was found in only 60 per cent. Evidences of vascular myelopathy were found in every instance of blindness. There were 3 patients with cord bladder symptoms and 4 with interosseous atrophy resembling amyotrophic lateral sclerosis. The majority of blind patients showed trophic changes of the skin, especially in the lower extremities.

COMMENT

The most significant deduction to be drawn from this study is that the duration of diabetes mellitus rather than the method of treatment is the most important factor in the development of degenerative changes. "It makes little difference how the diabetic is treated; if he lives long enough, he will develop one or another form of vascular disease." [12] This has been corroborated experimentally by Lukens and Dohan [13] in the observation of a lesion resembling that of intercapillary glomerulosclerosis in the first animal with pituitary diabetes to survive a period of five years. In 1930 Warren [14] claimed never to have seen an autopsy of "a diabetic whose disease lasted five years or more, free from arteriosclerosis, regardless of age." Eight years later he amended that statement, having found but 4 cases without this vascular damage. Priscilla White [15] admits "the incidence of degenerative complications in juvenile diabetes far exceeds expectation. . . . arteriosclerosis appears inevitable." Although in agreement with Lichtenstein's [11] free diet, I am constrained to point out the inadequacy of a mere ten years' observation as the basis for his claim of diabetic complications in "remarkably small degree." Wagener [5] emphasized the element of duration in finding an incidence of retinopathy in 76 per cent of patients under 30 years of age who had had diabetes for more than ten years.

The more obvious carbohydrate disturbance of what is commonly termed diabetes mellitus has overshadowed the generalized nature of the disease, the etiology of which is still unknown. The concept of vascular damage as a complication of diabetes must be amended in the light of all current observations; it is to be recognized rather as an integral manifestation of the basic disorder, an "associated concomitant of the disease." [16] Such a biologic approach to this problem was postulated by Dry and Hines [17] on the basis of "an inherent weakness . . . which affects both the insulin-producing tissues and the vascular system" with a common mechanism for the production of arteriosclerosis, retinopathy and neuropathy on the basis of involvement of the nutrient vessels to these structures. The diabetic patient provides unique material for the study of the phenomena of aging and associated degenerative diseases since it has been demonstrated that diabetes represents an acceleration of these processes.

CONCLUSION

1. Within a period of twenty-five years' duration of diabetes mellitus not 1 of 200 regularly examined patients escaped retinal hemorrhage, regardless of age of onset, severity of diabetes or type of treatment used.

2. Retinopathy usually presaged progressive vascular degeneration. Fifty per cent of patients exhibited hypertension and albuminuria at the time of earliest retinal hemorrhage.

3. Present day treatment of diabetes has failed to avert the accelerated vascular damage, which is an associated phenomenon of the disease and not a complication.

Venous Catheterization of the Heart.—Werner Forssman was the first to pass a catheter into the heart of a living patient, doing it first on himself with the help of a surgical colleague who made the incision over the median basilic vein in the antecubital space. Cournand and Ranges and their associates have used the method more than any group in this country, largely in the study of cardiovascular dynamics, particularly in shock. Their report in 1941 stimulated others to use the venous catheter, and at present a considerable literature has accumulated on the subject. Cournand reported 1,200 such examinations with no fatalities and no serious complications from the passage of the catheter. However, we know of one death in another institution following the injection of diodrast through the catheter in a patient who had been injected with the same medium ten days before.—Sosman, Merrill C.: Venous Catheterization of the Heart, *Radiology,* May 1947.

POTASSIUM DEFICIENCY IN DIABETIC ACIDOSIS

WILLIAM M. NICHOLSON, M.D.
and
W. STERRY BRANNING, M.D.
Durham, N. C.

Acidosis presents the most dramatic and dangerous of all the complications of diabetes mellitus. That the therapy in diabetic acidosis is unsatisfactory is shown not only in the mortality tables, but in the disagreements that arise whenever the subject is discussed. It is generally conceded that insulin is the prime need. Next in importance is correction of the disturbed water and electrolyte metabolism consequent to insulin deficiency.

Since 1936 the following plan of therapy has been used on all adult patients admitted to Duke Hospital with diabetic acidosis. When the diagnosis was made, blood was drawn for analysis and 50 units of unmodified insulin was given. This amount was repeated every half hour until the blood sugar level approached normal. On the ward gastric lavage and an enema were given, and external heat was applied. Subcutaneous and intravenous infusions of isotonic solution of sodium chloride were started and allowed to run at a rate of 750 to 1,000 cc. per hour. When the blood sugar level was decidedly reduced, a 10 per cent solution of dextrose was given intravenously. Sixty-seven per cent of the patients received sodium lactate solution along with the isotonic solution of sodium chloride.

Recently, Holler [1] reported a patient whose course resembled that of some observed in this clinic. There was a history of failure to take insulin for several days, resulting in acidosis and coma. On admission to the hospital, adequate therapy was given and improvement was prompt, only to be followed in several hours by generalized weakness and respiratory difficulty. The clinical syndrome of potassium deficiency was recognized, and the administration of potassium chloride was followed by dramatic improvement. In the light of this report, detailed study of 2 cases and a review of the data on all diabetic persons admitted here in a state of acidosis are presented.

REPORT OF CASES

CASE 1.—A white woman aged 28 was admitted in February 1939. She was known to have diabetes of six months' duration, and she had taken insulin in a haphazard manner. She had received no insulin for six days prior to admission, and two days before there had developed abdominal pain, nausea and vomiting. About eighteen hours before admission she became stuporous and could hardly be roused; for fourteen hours she had been comatose.

Physical examination disclosed that the blood pressure was 140 systolic and 92 diastolic, and the temperature 36.5 C. (97.7 F.). Characteristic Kussmaul respiration was present, and the odor of acetone was on her breath. Her skin was dry, cool and inelastic; the eyeballs were soft. The remainder of the physical examination was noncontributory.

Blood sugar determinations and the serum carbon dioxide combining power and potassium concentration were followed throughout her stay in the hospital.

After two hours of the usual treatment the patient began to rouse, and after eight hours she appeared quite well. About twelve hours later she began to complain of difficulty in breathing; this did not manifest itself objectively. The plasma carbon dioxide combining power was 40 volumes per cent and the blood sugar level was 84 mg. per hundred cubic centimeters. The patient complained of difficulty in swallowing, which progressed to inability to take anything by mouth, and respiration gradually became more rapid and shallow. Repeated physical examinations revealed nothing beyond an extreme degree of weakness of all muscles; the patient remained alert. Nikethamide was given frequently with no helpful effect. The blood sugar and serum carbon dioxide combining power had been approximately normal for twelve hours, and the urine had been free of sugar and acetone for twenty-four hours. The patient died in collapse thirty-seven hours after admission. No autopsy was obtained.

During the first twenty-four hours in the hospital she received by intravenous infusion 9,000 cc. of isotonic solution of sodium chloride. Dextrose was not given until after thirty hours, when the patient was already having respiratory distress.

As shown in chart 1, there was a progressive decrease in the serum potassium concentration, so that six and one-half hours before death it had reached 2.4 milliequivalents per liter (determined by the method of Kramer and Tisdal [2]).

CASE 2.—A white woman aged 60 was admitted in September 1946. This patient was the first person with diabetic acidosis admitted to Duke Hospital since the appearance of Holler's report. Six days before admission her insulin syringe was broken, and in order to punish her family for neglecting her she made no effort to replace it. She complained of abdominal pain and vomiting for three days before admission, and twelve hours before arrival she was found in deep coma.

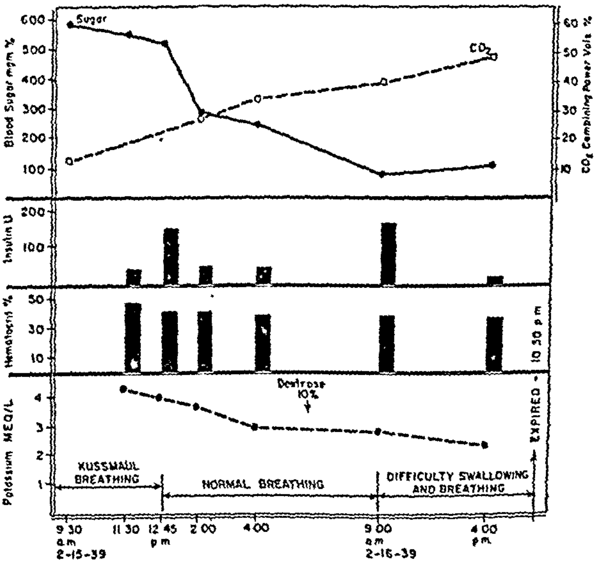

Chart 1 (case 1).—Results of laboratory tests showing decrease in the serum potassium concentration.

Physical examination disclosed the temperature was 37 C. (98.6 F.) and the blood pressure 80 systolic and 50 diastolic. Respirations were of the Kussmaul type. There were signs of extreme dehydration and an odor of acetone on her breath. She did not respond to painful stimuli. The remainder of the examination revealed essentially normal conditions.

The urine showed a strong reaction for sugar, acetone and diacetic acid. The blood sugar level and the serum carbon dioxide combining power are shown in chart 2.

Six hours after admission the patient roused; her respiratory rate was normal and she appeared much improved. At eight hours her blood sugar level was 324 mg. per hundred cubic centimeters, her carbon dioxide combining power was 34 volumes per cent and urinalysis showed traces of sugar and acetone with no diacetic acid. One hour later her respirations became shallow, rapid and obviously difficult. She received a 10 per cent solution of dextrose intravenously, with further impairment

of respiration. She was then given 0.6 Gm. of potassium chloride by mouth every half hour until 3.6 Gm. had been given. Within two hours her respirations were normal and subjectively she was greatly improved. The patient made an uneventful recovery.

The serum potassium concentration shown in chart 2 was determined in a flame photometer by the method of Barnes and associates.[3] The lowest concentration was 1.9 milliequivalents per liter, and at this time the patient was in respiratory distress. It must be pointed out that though the respiratory difficulty was present before the patient received dextrose, it became more pronounced afterward.

Table 1.—*Data on Diabetic Acidosis*

	Total Cases			Total Cases Less Deaths from Other Causes		
Mental State	Cases	Deaths	% Mortality	Cases	Deaths	% Mortality
Conscious	11	0	0	11	0	0

24	13	9	69.2	9	5	55.6
Totals	136	39	28.9	119	22	18.5

From its opening in 1930 to Jan. 1, 1946, 136 patients in diabetic acidosis have been admitted to Duke Hospital (table 1). Of the 39 who died, 17 had other disease that was the probable cause of death (table 2). When these are eliminated, the mortality rate for the remaining 119 patients is 18.5 per cent. This rate is much higher than any reported in recent years from other clinics. Only one recent report,[4] however, comes from a general hospital which draws its patients from rural communities where hospitalization is not immediately available.

Table 2.—*Causes of Death Other Than Diabetic Acidosis*

Pneumonia, lobar	5
Uremia	4
Septicemia	3
Renal abscesses	1
Carcinoma of cervix, radiation necrosis of bladder	1
Meningitis due to Hemophilus influenzae	1
Pelvic infection (septic course)	2
Total	17

The cause of death was determined clinically in 5 cases and by autopsy in 12

It has been shown by many observers[5] that neither the concentration of dextrose in the blood nor the serum carbon dioxide combining power has any relation with either the degree of acidosis or the mortality rate. We likewise could find no such relation, and these data are therefore not presented. It should be stated, however, that those patients who had been in coma longest exhibited a tendency to have higher concentrations of dextrose and lower carbon dioxide combining power.

The mortality rate in those patients who received sixth-molar solution of sodium lactate was lower than in those who received none (table 3). However, analysis reveals that these figures are not significant statistically.

We have defined the mental state of the patients as follows: Conscious, as the mental state of the patient who is fairly alert; drowsy, the patient who can be aroused by calling or by painless stimulation; semicomatose, one who can be aroused by painful stimulation, and comatose, one who cannot be aroused. Realizing the difficulty and in many instances the impossibility of estimating the length of time that a patient has been in a state of acidosis, we have, for uniformity, classified the patients in three groups according to time. In the first group, those less than twelve hours in coma, are included all patients who were conscious, drowsy, semicomatose and those who had been comatose for less than twelve hours. In the second group are those who were comatose for more than twelve hours and less than twenty-four, while in the third group are those who were comatose for twenty-four hours or longer. In our series the length of time in coma and the mental state were the factors of most prognostic value (table 1).

Table 3.—*Comparison of Mortality Rates With and Without Sodium Lactate Therapy*

	Sodium Lactate			No Sodium Lactate		
Hours in Coma	No. of Patients	Deaths	% Mortality	No. of Patients	Deaths	% Mortality
12	59	5	8.5	33	3	9.1
12 to 24	9	7	66.6	9	2	22.2
24	6	3	50.0	3	2	66.6

Among the persons who died from diabetic coma, there were 5 who ante mortem had normal blood sugar and serum carbon dioxide combining power and who showed no lesions at autopsy (table 4). In each of these cases it was noted that the patient had labored respirations, with or without difficulty in swallowing, and died in collapse. No potassium determinations were done in these cases. It can be conjectured that these patients, just as those whose history is given in detail, had abnormally low concentrations of serum potassium.

Table 4.—*Laboratory Data in Five Fatal Cases of Diabetic Acidosis*

Patients who died with normal values for carbon dioxide combining power and blood sugar. Autopsy showed no lesions.

History No.	Death, Hours After Admission	CO_2 Combining Power, Vol. %	Blood Sugar, Mg./100 Cc.

A-98866	14	53	141
B-20428	24	73	96

COMMENT

Smith[6] has reported that in dogs who are fed a diet that is low in potassium, paralysis of various muscle groups will result and, unless therapy is started, death in a state of collapse will occur. The administration of biotin will temporarily relieve these dogs, but potassium is necessary before any permanent improvement is noted. Furthermore, the serum potassium concentration is low. It is well recognized that in familial periodic paralysis the concentration of potassium in the serum is low, and that to prevent or to relieve an attack potassium is needed. We believe that the severe muscular weakness that we have seen in patients who apparently have recovered from diabetic acidosis is the result of potassium deficiency.

Several factors may combine to produce the reduction in the serum potassium concentration as noted in the cases reported here: (1) loss of potassium by diuresis and dehydration with resultant loss of intracellular stores of water and potassium; (2) loss of potassium as a result of the effect of insulin, and (3) reduction of serum concentration due to dilution by parenteral fluid with no outside source of potassium.

In careful balance studies on 2 diabetic subjects, Atchley and associates[7] demonstrated that during the period of insulin withdrawal there was an increase in t e excretion of potassium in the urine and that during the recovery phase the excretion of potassium was decidedly reduced. In our case 1 it was observed that 3.6 milliequivalents per liter of potassium were excreted during the first twelve hours. Unfortunately the excretion of potassium in case 2 could not be determined because the patient, who insisted on removing the catheter, was incontinent. In the 2 patients reported by Atchley, no great reduction of the serum potassium concentration at the beginning of the recovery period was found. No further determinations of the serum potassium were made until the end of the recovery period.

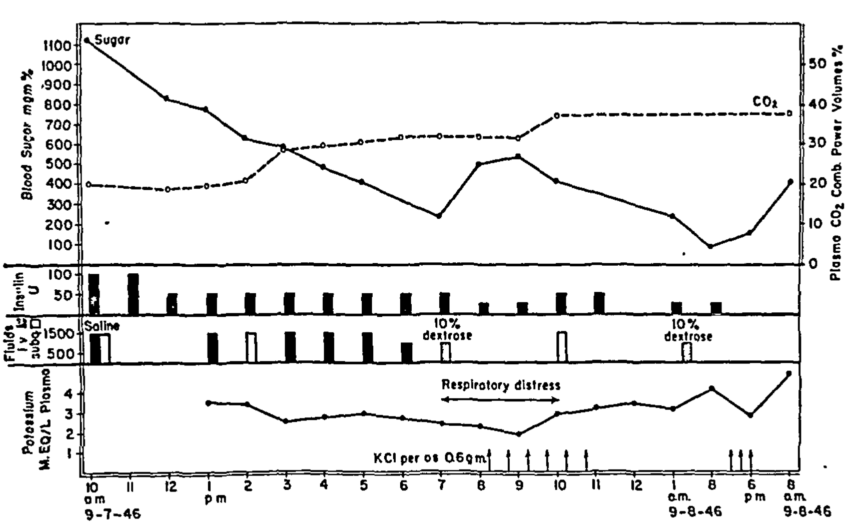

Chart 2 (case 2).—Laboratory data.

Elkinton and Winkler[8] have reported that in dehydration or diuresis not due to diabetic acidosis, loss of potassium in the urine takes place. They expressed the belief that there is also loss of intracellular water and potassium.

Harrop and Benedict[9] reported in 1923 that in patients with diabetes mellitus an injection of insulin produced a decrease of the serum potassium concentration. Briggs and associates[10] and Kerr[11] have shown that in normal dogs the administration of insulin produced a decrease in the concentration of potassium in the serum. Further evidence that insulin reduces the serum potassium has been shown by Aitken and associates in patients with familial periodic paralysis.[12]

In reconstructing the events that took place in the 2 cases reported here, it is apparent that there was a loss of potassium along with water, sodium and chloride, during the period in which the patients received no insulin. In addition to the loss of inorganic base and chloride due to diuresis, a considerable amount was lost in vomitus. After admission to the hospital, insulin and isotonic solution of sodium chloride in large amounts were administered. Further loss of potassium must have taken place at that time along with further decrease in the concentration because of dilution. This is partially confirmed by the fact that there was a steady and continued lowering of the serum potassium concentration while the patients were in the hospital. In case 1 the concentration had fallen to a critical level of 2.4 milliequivalents per liter six hours before death. Unfortunately, the significance of this deficiency was not recognized. In case 2 the serum potassium concentration fell to 1.9 milliequivalents per liter. Actually, enteric-coated potassium chloride by mouth had been given forty-five minutes before the serum was drawn for this determination. The drug had not been absorbed in quantities sufficient to be reflected in the serum at the time that the determination was made. Three hours after potassium chloride had been given to the patient the respiratory distress was completely relieved.

We believe that the potassium deficiency reported by Holler[1] and noted in 2 cases reported here is one of the factors responsible for the high mortality rate in cases of diabetic acidosis at this clinic. It appears that a longer time in coma allows more potassium to be lost from the intracellular stores and from the serum.

SUMMARY

1. Two cases of diabetic acidosis associated with a decrease in the serum potassium concentration are reported.

2. A review of data on patients admitted to Duke Hospital in diabetic acidosis reveals a mortality rate of 18.5 per cent, excluding deaths probably due to other causes.

COMPOSITE FREE GRAFTS OF SKIN AND CARTILAGE FROM THE EAR

COLONEL JAMES BARRETT BROWN, M. C., A. U. S.
St. Louis

LIEUTENANT COLONEL BRADFORD CANNON, M. C., A. U. S.
Boston

MAJOR CARL E LISCHER, M. C., A. U. S.
St. Louis

and

MAJOR W. BOWDOIN DAVIS, M. C., A. U. S.
Baltimore

Composite free grafts from the ear, comprising two surfaces of skin with cartilage between, have proved increasingly useful in the replacement of tissue lost from the nasal tip, nostril borders and columella. The use of a free transplant has made possible repairs in a single procedure with minimal resultant deformity of the ear. Thus, the risk of altering a normal feature in shifting a local flap or the need of multiple procedures in moving a distant flap have been eliminated in correcting these deformities.

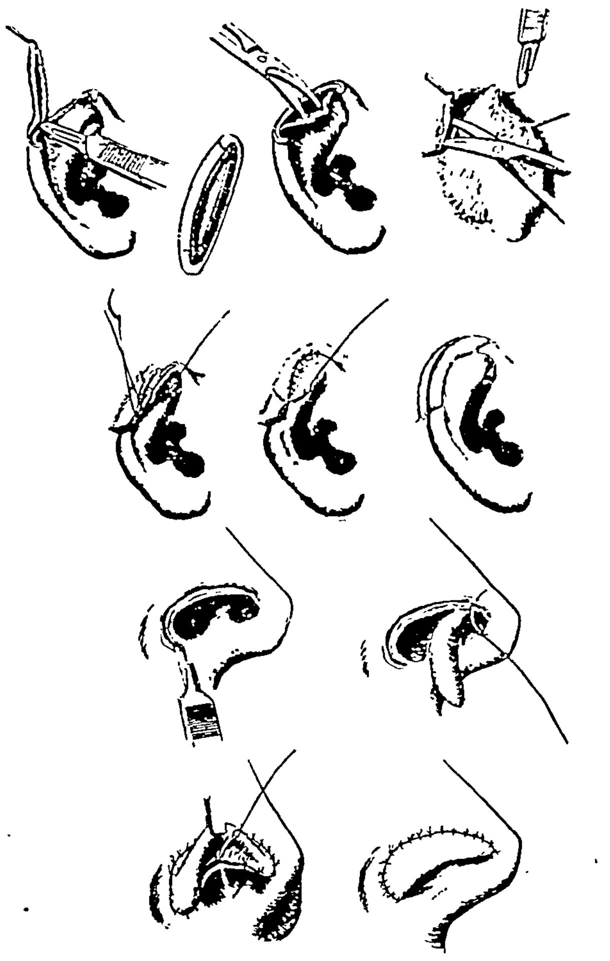

Fig. 1.—Steps in the repair of the nostril border with composite free grafts of skin and cartilage from the ear.

Losses from gunshot wounds, burns, injuries and surgical excision are all correctible by this method, but it is doubtful whether grafts over 1 cm. in width can be successfully transplanted. Since the length of the graft is not limited, the columella, tip and one ala can be restored with a single graft, which reproduces almost perfectly the normal curve at the apex of the nostril. To correct a short ala, the alar scar can be opened and a wedge shaped graft inserted; or a constricted nostril due to a burn can be opened by excision of the scar and repaired with a composite graft. A plaque of skin and cartilage is useful in losses at the tip, but an adequate overlap of skin must be left, since the blood supply develops from the margins, not through the cartilage. Adequate minute blood supply with as much well-vascularized surface as possible available for contact between the nose and the graft is necessary in preparation of the defect for the graft. The removal of all marginal scars will necessarily enlarge the defect but is important to insure an ample supply of blood. Any recent trauma or surgical procedure, such as resurfacing of the dorsum with a free skin graft, is sufficient reason to delay the use of the composite graft until all reaction has subsided.

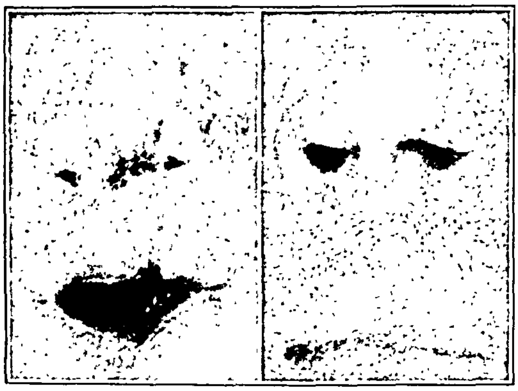

Fig. 2.—Restoration of columella, tip and ala in a single operation with composite free graft. Notching of upper and lower lips has been corrected.

A pattern of the final defect in the nose is helpful in selecting a suitable part of the ear for the donor area and important in accurate measurement of the graft. Portions of the normal ear with thin skin over the cartilage are best, but even a partially damaged ear may have enough suitable margin remaining for a large composite graft. The repair of the ear then is merely postponed until it can be combined with the nostril repair. If a long or wide graft is necessary, as in columellar-alar repairs, the rim of the helix is the only

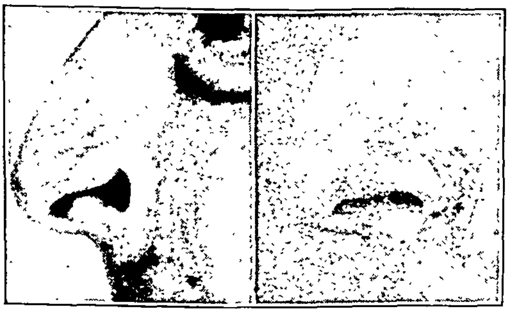

Fig. 3.—Restoration of margin and base of ala in a single operation with composite free graft.

Read before the Section on Laryngology, Otology and Rhinology at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 4, 1946.

This work has been done at Valley Forge General Hospital in association with Major Parke Scarborough, Major Edwin Shearburn, Captain Andrew Moore, Captain Joseph Murray, Lieut. Allyn McDowell and Lieut. Milton Edgerton.

possible source. Smaller grafts may be taken from the crus of the helix and flat grafts from the antihelix or rim of the concha. Separation of cartilage from skin in handling the grafts should be avoided.

Repair of the ear is performed by several methods. Larger excisions require repair with a scalp flap in which the open ear margin is buried. The pedicle is severed and the defect behind the ear grafted two or three weeks later. Smaller excisions can be repaired by direct closure or by a local flap or graft. The resultant deformities are not apparent.

The graft itself is accurately sewed in place usually with a few buried stitches for anchorage and fine stitches for skin approximation. In dressing the graft, adequate immobilization is secured by packing the nostrils and applying gentle but firm resilient pressure externally with an aluminum splint. Occasionally the grafts become discolored and even blister, but it has been observed that they generally recover, if carefully tended.

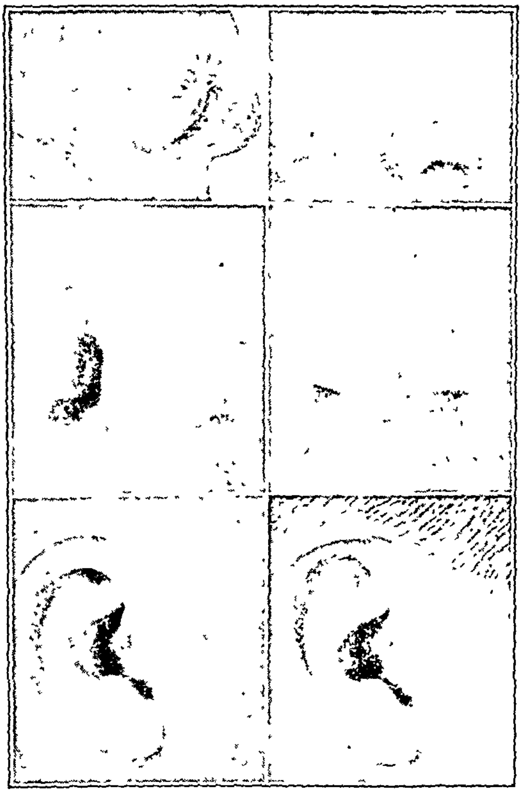

Fig. 4.—Large replacement of nostril defect by use of free composite graft of skin and cartilage in a single operation. Minimal deformity of ear with scalp flap.

SUMMARY

Composite free grafts of skin and cartilage from the ear have proved useful in correcting alar border, tip and columellar defects. Satisfactory repairs can be carried out in a single procedure by this method.

ABSTRACT OF DISCUSSION

Dr. William S. Kiskadden, Los Angeles: Those engaged in plastic surgery are constantly being asked what is new and what advances have been made. The case reports by Dr. Brown and Colonel Cannon represent something really new. Yet when one considers actually what has been presented it is seen that they have used only well known principles which have escaped the rest of us down through the years. They have used their own ingenuity, their technic and their imaginative surgical skill to great advantage. The war, of course, lent its aid in giving them a volume of cases in which, though 1 failure might have deterred them, they could proceed to a series as great as has been reported. There are other methods, of course, whereby repairs of this sort may be accomplished, but none, I think, that lend themselves as satisfactorily as this. Recently Dupurtuis, of Pittsburgh, brought out a procedure quite similar in technic wherein he utilized the lobe of the ear. Here again the matching of the tissue was comparable to the matching that was obtained by Dr. Brown and Colonel Cannon. The advantage is that the lobe can be simply and easily repaired. Another method offers itself. It entails additional operative procedures, but occasionally with advanced scarring and an inadequate blood supply, possibly secondary to a rather severe burn, possibly secondary to the bringing down of a forehead flap, tissue from the ear can be still utilized. This method, I believe, was first put forward by a South American and consists in implanting into the palmar aspect of the thumb that amount of tissue which needs to be employed in the graft. Obviously, recourse to such a procedure would only be taken because the surgeon feared that the blood supply of the recipient area would not take the cartilaginous and double skin flap. The utilization of rotation flaps, either from above the nose or from the cheek, likewise should not be lost sight of. I do not believe that any one operative procedure will always answer the problems that attend these apparently minor defects, yet defects which are extremely difficult to repair.

Dr. Walter B. Macomber, Albany, N. Y.: It is a privilege to discuss this paper of Dr. Barrett Brown and Colonel Cannon. It demonstrates what a surgeon must have for the advancement of plastic and reconstructive surgery, forever looking for something new to help to improve technics of years past. It is a one stage procedure as far as the reconstruction of the nose is concerned, but in many cases the ear means a two or more stage procedure, and reconstruction of the ear is decidedly difficult. It is one of the hardest parts of the body to reconstruct. Most nasal deformities during this war were secondary to burns which did not spare the vulnerable ear, thereby preventing the use of this donor site. There was so much scarring that the little tissue left could not be used as a free graft. Nasal deformities, except those secondary to malignancy, are usually associated with extensive scarring, and the recipient site is not conducive to the taking of even a thick split graft, let alone a composite graft. As stated by Colonel Cannon, the size of the graft will lend itself to the repair of relatively small defects. The possible chances of losing the graft in hands other than those of Dr. Brown and Colonel Cannon would create a major deformity of the ear, provided the deformity of the nose was quite large.

Col. Bradford Cannon, Boston: There is not much for me to add except to thank the two men who have been kind enough to discuss this paper and to say that I hope those who are interested in plastic surgery of the nose will try this procedure and see whether it is not as simple and satisfactory as any procedure which was ever utilized in correction of these deformities.

Emotion and Illness.—Every person reacts emotionally in his own fashion to environmental demands, whether these include accidents, infections, laws, enforced association, fishing trips, garden clubs or bad weather. The significant fact is that every one reacts and that every one develops body symptoms if the emotional stimulus is sufficiently strong. . . . Ordinarily the symptoms are of short duration, subsiding with the removal of the stimulus. If adjustment to the environmental demands is faulty, the individual takes recourse to anxiety, headaches, nausea and vomiting, amblyopia or obsessions. Individuals suffering from psychosomatic ailments do not always show manifest symptoms of emotional imbalance; therefore the psychic factors which are underlying or complicating their condition often remain undetected, and his fact may delay or prevent recovery.—Caveny, Elmer L.: Emotion: The Etiologic Relation to Illness, Naval Medical Bulletin, May-June 1947.

Clinical Notes, Suggestions and New Instruments

FATAL PEDICULICIDE POISONING (ABSORPTION THROUGH SCALP)

BENEDICT SKITARELIC, M.D.
Cumberland, Md.

The following is the report of a fatal case with autopsy observations in which death resulted from the use of a pediculicide containing picrotoxin and veratrine. No other similar case has been found in the medical literature.

Picrotoxin and veratrine are commonly used as ointments, powders or liquid preparations in the treatment of pediculosis, scabies and other parasitic diseases of skin in both man and animals. These drugs if used cautiously are effective, but when they are used indiscriminately there is considerable danger because of the large areas of skin available for absorption of the compounds. The pediculicide used in this case, "kil-ve," has for its active ingredients fishberry and sabadilla seed, which are extracted in isopropyl alcohol 72 per cent and water 27.5 per cent.

Picrotoxin is derived from cocculus indicus (the seed of Anamirta paniculata, or fishberry; used for poisoning fish, adulterating beer, and in "knockout drops"). The external use against pediculi has given rise to toxic effects.[1] The symptoms of poisoning in man consist of burning sensation, nausea, salivation, cold sweat, pallor, colic, vomiting, diarrhea, palpitation and shallow respiration; the pulse rate may be slowed or quickened. These are rapidly followed by confusion, stupor and unconsciousness. After one-half to three hours, trembling, clonic and tonic convulsions appear. These generally pass into paralysis and death by asphyxiation.

Picrotoxin ⅓ grain (0.022 Gm.) has caused unpleasant symptoms, and from experiments on animals it is thought that 2 or 3 grains (0.13 or 0.195 Gm.) would be a dangerous dose for man. Death is said to have resulted, however, from 36 grains (2.4 Gm.) of powdered berries; this would equal about ⅓ grain (0.022 Gm.) of picrotoxin. An interesting sidelight is that patients poisoned by barbituric acid derivatives are able to take doses of picrotoxin ranging from 1.079 to 2.296 Gm.[2]

Death from gastrointestinal absorption may occur within thirty minutes to three hours. In Thompson's case,[3] in which the drug was absorbed from the skin, death occurred in six hours.

The postmortem observations are those of asphyxia with hyperemia and edema of the lungs and brain. No really characteristic findings have been observed in man.

Veratrine is a mixture of alkaloids extracted from sabadilla seeds. Therapeutically it is used as a counterirritant in neuralgic conditions. In the form of sabadilla seeds it is used as a parasiticide against pediculi capitis. The irritation is severe, and absorption has caused serious symptoms.[4] When veratrine is taken internally toxic symptoms may appear in man in twenty minutes or be delayed for an hour or more. Symptoms begin with prickling and burning of the mouth, followed by sensation of warmth and burning in the stomach. There is great thirst and difficulty in swallowing. Then follows salivation, nausea and persistent vomiting. Colic and abdominal pain may also be present. Death is due to cardiac and respiratory failure. Postmortem observations are not characteristic, although congestion of the gastrointestinal tract and brain are found.

REPORT OF CASE

History.—V. B., a white girl aged 2 years, was first seen in the Baltimore city mortuary. The history obtained from the mother was that the child had head lice and that for the past month she had been using a pediculicide called "kil-ve." The mother claimed that the child had never been sick and had been active before death. She put her to bed at 4 p. m. and when she returned at 7 p. m. the child was dead.

The mother denied that the child could have taken any of the pediculicide by mouth, either directly or indirectly. According to her story she used the whole 2¾ ounce (81 cc.) bottle (directions called for 2 or 3 tablespoonfuls, 30 to 45 cc.) in one application. She could not give the time of the last application, but the child's hair contained the preparation when it was examined in the mortuary.

The mother's story was not taken as too reliable.

Autopsy.—The body was that of a well developed and well nourished white girl whose hair was covered with a myriad of live lice. The hair pulled out easily, taking with it patches of scalp. There was no external evidence of injury or violence. The pupils were central and equal. There was a slight frothy secretion from the nose and mouth. The neck contained no enlarged glands. The chest and abdomen were of normal contour. The extremities and genitalia showed nothing of note

The body was opened, and all the organs were normally disposed. The pleural cavities were dry. The peritoneum was smooth and glistening, and no free fluid was present.

The heart showed slight right ventricular dilatation, otherwise no abnormality was present. The myocardium was of good tone.

The lungs were somewhat congested and exuded a frothy fluid. Their external surfaces were smooth. There was a slight injection of the larger bronchi. Vascular or bronchial obstruction was not present.

The thymus was small and on section revealed normal architecture.

The liver was paler than is usual. The external surface was smooth, and on section there was a uniformity of structure.

The spleen was of normal size, and the pulp was somewhat friable.

The adrenals both externally and on cut section showed nothing of note.

The kidneys were of normal size and consistency. On section there were definite demarcations between the cortices and medullae. The pelves were pale. The ureters were of normal caliber. The bladder contained about 300 cc. of pale urine. The mucosa was pale, and the wall was of normal thickness.

The stomach contained about 30 cc. of bile-stained liquid and food particles. The mucosa showed no evidence of erosion or inflammation. The intestines manifested no gross changes.

The brain exhibited pronounced edema as evidenced by flattening of all convolutions. No exudates or hemorrhages were present.

Microscopic Observations.—Except for the liver, lungs and brain there were no remarkable or significant changes in any of the organs. The brain showed much edema. The cells were well preserved. The liver manifested moderate cell necrosis around the central veins. This process was no more pronounced than that seen in congestive changes. Various sections taken from the lungs all exhibited fairly well defined edema and congestion. The alveoli were filled with acellular fluid. The alveolar walls were thickened by edema and dilated vessels containing red blood cells. No evidence of inflammation was present.

Toxicologic Examination.—The stomach contents, liver and brain were used in the toxicologic examination.[5] The stomach contents were negative. The extracts of liver and brain both revealed the presence of picrotoxin and veratrine. The residue from 120 Gm. of liver yielded 1 mg. of picrotoxin. Veratrine was found only in traces.

[5] Examination by Henry C. Freimuth, Ph.D., Office of Medical Examiner, Baltimore, Md.

COMMENT

It can be concluded, in the absence of any changes in the stomach or intestines and in view of the negative stomach contents, that the presence of picrotoxin and veratrine in the liver and brain was the result of absorption from the scalp. The concentration of picrotoxin was sufficient to cause death. The role played by the traces of veratrine is believed to be of minor importance in this case.

This case illustrates the importance of absorption from the skin. The various preparations which are used for treatment of the skin and scalp are no doubt partially absorbed. Care must be taken in the selection and use of these preparations. Work on the permeability of skin conclusively shows that many substances are absorbed and may be recovered in blood, urine or exhaled air. Lipoid solubility is not the only condition for absorption by the skin; inorganic salts are also absorbed in small quantities.[6]

SUMMARY

Preparations containing picrotoxin, veratrine or a combination of both are frequently used in treatment of parasitic conditions of the skin. Absorption through the skin may give rise to toxic symptoms and even death. The manner of death, the presence of pulmonary and cerebral edema, the absence of any specific observations at autopsy and the recovery of the drug from the organs are compatible with the action of picrotoxin and veratrine.

MYOKYMIA—A CAUSE OF "RESTLESS LEGS"

RICHARD L. MASLAND, M.D.
Winston-Salem, N. C.

The purpose of this article is to point out an entity, not previously considered, which can give rise to the complaints described as "restless legs." This manifestation has been termed myokymia. It is characterized by the occurrence of irregular fascicular twitching of the muscles.

It is observed most frequently in neurotic persons, in those in debilitated states and in the elderly. The patients complain of a crawling sensation in the skin of the calves and thighs and occasionally of other parts of the body. This is most disturbing when the patient is fatigued and is relaxing, as on retiring. The sensation of crawling under the skin is often accompanied by an unpleasant fatigued aching of the muscle. The twitching tends to disappear during the night, to reappear shortly after waking and to increase during the day. It is intensified by exercise, nervous tension or cold. Persons suffering from this condition are also subject to muscular cramps, especially if the feet are cold or if the muscles are contracted strongly in the shortened position.

The fasciculation is most easily observed by having the patient lie face down with the calves exposed and in a good light. Under these conditions, and with the feet held in plantar flexion by the bed, the muscles of the calf are shortened and relaxed. Observation over a period of from one to five minutes will disclose the occurrence of occasional flickering movements of the skin which are caused by fasciculation of the underlying muscle. If the muscle is tapped with a reflex hammer the twitching is increased.

Although it has been stated by some observers[2] that the twitching of myokymia can be distinguished from the fasciculation observed in anterior horn cell disease, others[3] have been unable to make this distinction either by clinical observation or by electromyogram. However, the two conditions can be distinguished by the lack of muscular atrophy in myokymia as well as by the lack of reflex abnormalities. It has also been suggested that twitching of this sort is always a precursor of atrophy due to organic disease of the nervous system. It is true that in amyotrophic lateral sclerosis twitching may appear several months before there is evident weakness or atrophy. However, the occurrence of twitching of the muscles of the calf is a not infrequent occurrence in normal persons, and I have personally followed a patient with active myokymia for ten years and have found no evidence of organic disease.

The administration of small doses of neostigmine bromide (0.5 mg.) causes a great increase in the twitching,[4] and this fact suggests that the fasciculation produced by the drug and that observed in myokymia have a common origin. This probably represents either a high level of acetylcholine at the nerve ending or possibly an increased irritability of this structure.[5] The fasciculation observed in anterior horn cell disease probably has a similar peripheral origin, although the mechanism of its development may be different.[5b]

The twitching of myokymia is disturbing only to the neurotic patient, and many other persons are completely unaware of it. Treatment is therefore primarily a matter of reassurance and redirection of the patient's interest away from this unimportant symptom. The administration of small subcurarizing doses of a curare preparation will stop the twitching at a dosage level far less than that required for curarization,[6] and it is probable that the use of the newly developed preparation of curare in oil[7] would be effective in this condition. It is questionable, however, whether such treatment is justifiable in view of the lack of importance of the symptom involved.

Council on Foods and Nutrition

ACCEPTED FOODS

The following foods, which are used primarily in the feeding of infants and small children, have been accepted as conforming to the Rules of the Council on Foods and Nutrition of the American Medical Association.

JAMES R. WILSON, M.D., *Secretary.*

PREPARATIONS USED IN THE FEEDING OF INFANTS

Libby, McNeill and Libby, Chicago.

LIBBY'S STRAINED AND HOMOGENIZED SQUASH consists of squash, salt and water.

Analysis (submitted by manufacturer).—Total solids 9.05%, moisture 90.95%, protein (N × 6.25) 0.75%, fat (ether extract) 0.05%, ash 1.14%, crude fiber 0.85%, carbohydrates other than crude fiber (by difference) 6.26%.

Calories.—0.29 per gram; 8.23 per ounce.

Vitamins and Minerals.—	Per Hundred Grams
Vitamin A	1,562 U. S. P. units
Thiamine	0.013 mg.
Riboflavin	0.042 mg.
Ascorbic acid	4.90 mg.
Niacin	0.420 mg.
Salt	700.00 mg.
Calcium	44.10 mg.
Phosphorus	12.20 mg.
Iron	0.30 mg.

Libby, McNeill and Libby, Chicago.

LIBBY'S STRAINED AND HOMOGENIZED VEGETABLES WITH BACON AND BARLEY consists of water, tomato juice, carrots, sweet potatoes, potatoes, bacon, barley, celery, onions and salt.

Analysis (submitted by manufacturer).—Total solids 14.73%, moisture 85.27%, protein (N × 6.25) 1.59%, fat (ether extract) 3.20%, ash 0.96%, crude fiber 0.47%, carbohydrates other than crude fiber (by difference) 8.51%.

Calories.—0.71 per gram; 20.16 per ounce.

Vitamins and Minerals.—	Per Hundred Grams
Vitamin A	4,301 U. S. P. units
Thiamine	0.038 mg.
Riboflavin	0.022 mg.
Ascorbic acid	2.40 mg.
Niacin	0.61 mg.
Salt	670.00 mg.
Calcium	15.70 mg.
Phosphorus	34.70 mg.
Iron	0.63 mg.

This report is the forty-seventh annual compilation of information and statistics on medical education in the United States and Canada by the Council on Medical Education and Hospitals of the American Medical Association.

For the first time in several years the report contains specific information concerning the financial support of undergraduate medical education in this country. In addition to the various statistics concerning medical schools, students and graduates that are regularly included in this report, several subjects of present interest are discussed. These include formal basic science training for hospital residents, the academic performance of veterans, the production of physicians during the past ten years and the continuation of the accelerated program.

For the first time since 1942 the paper supply has permitted the inclusion of a detailed summary of the requirements of the various examining boards in the medical specialties. The full text of the "Essentials of Approved Residencies and Fellowships" as revised to June 9, 1947 is also presented.

The hospitals approved for internships, residencies and fellowships have been listed. Separate reprints of these lists are available for distribution in addition to the reprints of the complete report.

The data presented in this review are obtained from official reports The Council and The Journal express their sincere gratitude and appreciation to the officers of the medical schools, hospitals and other agencies whose cordial and continuing cooperation makes possible each year the compilation and presentation of this body of fundamental information concerning medical education in the United States and Canada.

Medical School Calendars

This 1947 Educational Number presents data for the 1946-1947 academic year. Some irregularity of medical school calendars persists as a consequence of the accelerated program. It is necessary therefore that the sessions that are reported in this Educational Number be identified by specific dates for each school. This has been done for the four year schools in the United States in table 1, for the medical schools in Canada in table 2 and for the schools of the basic medical sciences in the United States in table 3.

Freshman classes for the academic year 1946-1947 began in September or October in all but six schools which had admitted classes earlier in the year. Four schools (Louisville, Minnesota, Marquette, Mississippi) admitted two freshman classes.

Tables 1, 2 and 3 also give the dates of the next two entering freshman classes. For the academic years 1947-1948 and 1948-1949 freshmen will be admitted in September or October by all but two schools. Utah has established June as the month for the admission of freshmen in these years, and Tennessee will admit freshmen quarterly in September, December, March and June. Mississippi, in addition to admitting a class in September, is planning to admit a second freshman class in January or February as a regular practice.

The data on graduates are for the thirteen month period June 1, 1946 to June 30, 1947. All the four year schools graduated at least one class during this period. Ten schools, excluding the schools on the quarter system, graduated two classes. For four of these schools (Alabama, Stanford, Buffalo and Syracuse) no graduations were reported in the 1945-1946 Educational Number. The other six schools graduated classes early in the period covered by that number.

In table 4 is recapitulated the number of graduations, with dates, which have been held by each of the medical schools in the United States since July 1, 1942, the date on which most schools began wartime acceleration. During the five year period July 1, 1942 to June 30, 1947 a total of 406 graduations have been held. This figure does not include the graduations at Tennessee, which were on a quarterly schedule.

On the prewar schedule of one graduation class for each medical school per calendar year, the number of graduations that would have normally been held during this period by the medical schools in the United States, excluding Tennessee, would have been 136. The accelerated program thus made possible the training and graduation of seventy additional classes in the five year period.

TABLE 3.—*Admission Calendars of Schools of the Basic Medical Sciences in the United States*

SCHOOL	Freshman Classes Included in This Educational Number: Date of First Class	Date of Second Class	Dates of Next Two Entering Classes

[1] Graduates students quarterly, March, June, September and December.

The dates for the next two graduations for the various schools are shown in tables 1, 2 and 3. During the academic year 1947-1948 seventeen schools, excluding the schools on the quarter system, will graduate classes earlier than May or June. Three schools (Louisville, Minnesota and Marquette) will graduate two classes during the period July 1, 1947 to June 30, 1948. Alabama will have no graduating class during this period. This school did not develop its four year program until July 1943. The first two classes admitted to the four year program were on the accelerated schedule and completed their work in three calendar years. The graduation of both these classes is reported in this number. Alabama has now discontinued acceleration and in the process of reconversion will not graduate its next class until June 1949.

The estimated number of graduates for each medical school in this country and the distribution of graduations by months for the period July 1, 1947 to June 30, 1948 are shown in table 5.

In 1948-1949, according to present schedules, all but three schools (Bowman Gray, Ohio State and Utah) will hold their graduations in May or June.

Continuation of the Accelerated Program

During the academic year 1946-1947 eighteen schools continued to have an accelerated program either in part or in whole. In certain schools all classes were on the accelerated program, in others only one or two. Acceleration was required of all students in the classes concerned in some schools; in other schools the students could elect to follow an accelerated schedule if they so desired. The data with respect to accelerated programs in 1946-1947 and 1947-1948 are summarized in table 6.

Four schools (Louisville, Minnesota, Tennessee and Utah) are planning to continue an accelerated program

for all four classes, at least for the next two years. Three schools (Duke, Bowman Gray and Chicago) will allow students to elect an accelerated program for any or all of the four years. One school (Northwestern) will offer a quarterly schedule in the junior and senior years so that students who elect to do so may complete their courses approximately six months in advance of the regularly scheduled graduation. Mississippi, a two year school, will be on an accelerated program that will enable a student to complete the two years' work in approximately eighteen months.

For the other schools the acceleration of one or more classes during 1946-1947 and 1947-1948 is a temporary measure in the process of deceleration. Acceleration will probably be discontinued in these schools no later than the end of the academic year 1947-1948.

At least eighteen schools will offer a senior year in 1947-1948 that will extend for forty-five weeks or longer. In certain schools the extension of the senior year is planned as a permanent feature. In other schools it is a temporary arrangement associated with deceleration. This trend toward a longer senior year is of considerable interest. Experience may demonstrate that it is a satisfactory method of providing in the curriculum for important subjects that cannot be allotted adequate time in the conventional thirty-two or thirty-six week senior year.

1. Admits freshmen quarterly.
2. Offers quarterly schedule for all four classes.
3. School of the basic medical sciences.
4. Offers quarterly schedule for juniors and seniors.

Approved Medical Schools

Medical schools in the United States approved by the Council on Medical Education and Hospitals of the American Medical Association are shown in table 7; those in Canada are listed in table 8. The approved schools of the basic medical sciences in the United States and Canada are shown in table 9.

One new school, the Medical College of Alabama, has been added to the list of approved medical schools in the United States. In 1943 the University of Alabama School of the Basic Medical Sciences inaugurated a four year program and changed its name to the Medical College of Alabama. The first junior class was enrolled in June 1945 and the first senior class graduated in October 1946. With its four year program now fully in operation, this school has been transferred from the list of approved schools of the basic medical sciences to the list of approved medical schools.

The Hahnemann Medical College in Philadelphia is on probation, as are also the basic science schools of North Dakota and South Dakota.

Tables 7, 8 and 9 give the quantitative premedical requirements effective next year for each school, the enrolment by classes for the academic year 1946-1947 and the total attendance, which does not include the students in the required intern year. The number of graduates from June 1, 1946 to June 30, 1947 is also given for each school.

For the Canadian schools (table 9) enrolments are also given for premedical students in the medical school, as well as for students in a fifth medical year and the required intern year.

For each school the name of the dean or executive officer is given. Since the publication of last year's Educational Number the executive officers have changed in thirteen of the eighty-seven medical and basic science schools in the United States and Canada. The following schools have appointed new executive officers: Arkansas, Yale, Georgetown, Emory, Illinois, Boston University, Oklahoma, Medical College of Virginia, Marquette, North Dakota, Western Ontario, Toronto and McGill.

Enrolments 1946-1947

Enrolments for the academic year 1946-1947 for the medical schools in the United States are shown in table 7, for the medical schools in Canada in table 8 and for the schools of the basic medical sciences in the United States and Canada in table 9. The enrolment figures in these tables are recapitulated in table 10.

Five of the four year schools (Alabama, Louisville, Minnesota, Utah and Marquette) and one of the two year schools (Mississippi) had two separate classes enrolled in one or more years of the medical school course during 1946-1947.

The total enrolment, excluding students taking a required intern year, in the seventy medical and seven basic science schools in the United States was 23,900. This enrolment is 684 greater than the enrolment for 1945-1946 and is only 766 less than the enrolment of 24,666 for the 1944 "second session," the largest enrolment since 1910.

If the 1,131 students enrolled in the additional classes during 1946-1947 were not included, the total enrolment would have been 22,769. This figure is larger than the enrolment in any of the years from 1910 to 1942 with the exception of 1934 and 1935 (table 21).

From these figures it is apparent that in the first approximately normal postwar year the enrolment in medical schools in the United States has been maintained at nearly a peak figure. It is thus clear that the record of medical education in reconverting to a peacetime status can be compared favorably to the reconversion efforts of other groups in our society.

The total enrolment in the Canadian schools, including one basic science school, was 2,982, which is 412 greater than in the preceding session. There were 399 premedical and 34 fifth (not intern) year students in the Canadian schools. These figures are included in the "total" column of table 8 but not in the "total" column of table 10.

Students in a required intern year numbered 582 in the United States and 170 in Canada.

* On probation.

† 90 semester hours for veterans.

‡ Two years for veterans.

§ Figures are for two graduating classes and include senior students reported in 1946 Educational Number.

Intern enrolment not included in total column.

Only five medical schools in the United States had 500 or more students enrolled, excluding those in the intern year. Illinois with 635 students had the largest enrolment. Jefferson had 606, Northwestern 517, Tennessee 512 and Michigan 500.

Eight schools in this country had enrolments under 200: Woman's Medical had 151 students, Vermont 155, Bowman Gray 172, Syracuse 182, Albany 183, Utah 186, Vanderbilt 193 and Alabama 197 The figures for Utah and Alabama include the two senior classes that were in session during 1946-1947.

In Canada the largest enrolment occurred at Toronto with 573. This number does not include 338 students in the premedical years The smallest enrolment in Canada was at Alberta, with 155 students

In the schools of the basic medical sciences in this country the total enrolment was 429. Mississippi with 86 students and North Carolina with 79 students had the largest enrolments. Dartmouth with 34 students had the smallest enrolment

In table 11, enrolments in the various classes in the medical and basic science schools in the United States are given for each academic session since 1930-1931 Compared with the figures for 1945-1946 there were 504 more freshmen, 175 fewer sophomores, 16 more juniors and 339 more seniors enrolled in 1946-1947.

It is of considerable interest to compare the size of the freshman classes for 1946-1947 in the various medical schools with the freshman enrolments reported by each school for 1941-1942, the last prewar year. In four schools the figures were exactly the same In thirty-five schools the 1946-1947 freshman enrolment was greater and in thirty-seven schools it was less Comparative figures are not available for one school, Southwestern Medical College, which was not founded until 1943.

* On probation
a Beginning date of additional freshman class January 1947

Of the thirty-five schools with increased freshman enrolments, the increase was less than 10 per cent in twenty-one and 10 per cent or greater in fourteen. Of the thirty-seven schools with decreased enrolments, the decrease was less than 10 per cent in twenty-five and 10 per cent or more in twelve.

It should be noted that prior to 1942-1943 the totals shown in table 11 are somewhat higher than the sum of the figures for the various classes. This discrepancy resulted from the inability of certain schools to classify strictly their students into the conventional graded classes.

* Includes additional classes.

In table 12 is shown the total number of students in the United States taking a required intern year and the total number of students taking such work for each of the academic years since 1930-1931.

Veterans in Medical Schools

Of the 23,900 students enrolled during 1946-1947 in the medical schools and schools of the basic medical sciences in the United States, 13,308, or 55.6 per cent, were veterans. Forty-six of the veterans were women. In table 13 is shown the composition of the student bodies for each of the medical schools and schools of the basic medical sciences in the United States for 1946-1947. These figures are recapitulated by classes in table 15.

The highest percentage of veterans was in the freshman class, of which veterans comprised 62.8 per cent of the students enrolled. The percentage of veterans for the other classes were sophomores 53.7 per cent, juniors 48.9 per cent, seniors 55.9 per cent.

With respect to the scholastic performance of veterans in the 1946-1947 freshman class, twenty-three schools reported that the veterans did better work than the nonveterans, fifty-one schools reported no significant difference between the work of the veterans and nonveterans, one school reported that the nonveterans did better work, and two schools were unable to express an opinion.

Almost the same distribution of opinion obtained with respect to the comparison of the freshmen veterans with the freshmen of prewar years. Twenty-six schools reported that the veterans were better students, forty-six could find no difference, three schools said that the prewar freshmen were better students and two schools were unable to comment on the question.

While the opinions expressed by several schools were based on impressions rather than on statistical data, it would seem clear that the veterans are proving to be capable students.

Distribution of Students by Sex

In table 14 the students enrolled in all the medical and basic science schools in the United States and Canada during the academic year 1946-1947 are classified according to sex. The same table also classifies according to sex the graduates of the four year schools during the period June 1, 1946 to June 30, 1947.

The number of men enrolled totaled 24,874 and the number of women 2,441. Four schools had no women students: Georgetown, St. Louis, Dartmouth and Jefferson. One school, the Woman's Medical College, had no men students.

Table 16 gives the numbers and percentages of women medical students and graduates in the United States since 1905. In 1946-1947 there were 2,183 women students, or 9.1 per cent of the total students enrolled. This is the highest absolute as well as relative number of women medical students in the United States on record. The highest percentage of women was in the freshman class, in which women students numbered 11.1 per cent. In 1944-1945 there were only seven schools in addition to the Woman's Medical College that had more than 30 women enrolled. In 1945-1946 there were seventeen and in 1946-1947 there were twenty-four. In Canada, Toronto had 112 women students.

It is clear from the figures in table 16 that the opportunity for women to study medicine in the United States has almost doubled in the past three years. A change in the direction of this trend, however, will probably be observed next year, since it is estimated that about 9 per cent of the entering classes in 1947 will be women, as compared with 11 per cent in the 1946 class.

Geographic Source of Freshman Students 1946-1947

In table 17 is indicated the residence of students in the first 1946-1947 freshman class of each medical and basic science school in the United States and Canada. In table 18 the same information is given for the students enrolled in the second freshman class for those schools that admitted two freshman classes during 1946-1947. It is admitted that the residence of certain students may be of brief duration, so that their real geographic source may not be revealed by their residence on entering medical school. On the other hand, the birth place of students is probably no better a criterion of geographic origin, since appreciable numbers of people have permanent residence elsewhere than in the states of their birth.

enrolment figures given in preceding tables because table 17 employs the figure for the first class of premedical students at Queen's and Toronto, since these students are already registered in those schools.

In table 19 is shown the number of first year medical students from each state per hundred thousand inhabitants. *This calculation* employed *only the* enrolment statistics in table 17.

In previous years the statistics have shown that states with and states without medical schools have sent almost identical proportions of their populations to medical schools. This year the figures reveal a somewhat different situation. The twelve states without medical schools had an average of 3.5 students per hundred thousand of population in the 1946-1947 freshman classes of the various medical schools, while those states with medical schools had an average of 5.2 students per hundred thousand of population enrolled as freshmen. The explanation for this change is not immediately apparent. It does not appear to be the result of any general change in the policy of schools with respect to the admission of nonresident students.

Table 18.—*Residence of Freshman Medical Students*

A comparative study of resident and nonresident enrolments in 1941-1942, the last prewar year, and in 1946-1947 reveals no especial differences. In 1941-1942 the enrolment of the state and municipal institutions included 17.4 per cent out of state students. In the same year the enrolment of private medical schools included 52.9 per cent nonresident students.

Of the freshman students admitted by state and municipal schools in 1946-1947, 14.8 per cent were nonresidents. In the private schools 51.4 per cent of the freshmen were out of state students.

It is to be hoped that, if a trend is developing for medical schools to restrict admission to residents of their own states, it will be temporary and short lived. While it is easy to understand the pressures that might lead to the adoption of such a policy, it must be seriously questioned whether such a practice would be in the best interest of the schools themselves or of medical education in the country as a whole. If the admission of nonresident students should be narrowly restricted, it would undoubtedly encourage the development of medical schools in a number of states which are not in a position to establish and maintain acceptable medical schools.

In table 20 is recapitulated the number of resident students, students from other states, students from United States territories and possessions, Canadian students and foreign students enrolled in the first 1946-1947 freshman class in each school in the United States and Canada.

Six schools did not admit any out of state students in 1946-1947. They were Alabama, Georgia, Mississippi, South Carolina, Texas and West Virginia. These schools have frequently enrolled only residents in the past, although in the preceding two years every medical school in the United States accepted some out of state students. Seven schools admitted only 1 or 2 out of state students. Twenty-three schools admitted more nonresident than resident students, and one school admitted an equal number of residents and nonresidents.

Of the 964 beginning students in Canada, only 13 came from the United States. Nineteen freshman students from Canada were enrolled in the schools in this country It is apparent that the extensive exchanges of students between these neighbor countries which existed before the war have not yet been reestablished.

There were 88 freshman students from the territories and possessions of the United States, none of whom were enrolled in Canada. A total of 73 students from foreign countries was enrolled in freshman classes, 54 in the schools of this country and 19 in Canada. The largest number, 11, was enrolled in the Howard University College of Medicine.

Graduates

The last columns of tables 7 and 8 give the number of graduates from each medical school in the United States and Canada respectively from June 1, 1946 to June 30, 1947. During this period there were 6,389 graduates in the United States and 567 in Canada. As already mentioned, ten schools in the United States graduated two classes during this period.

The total students and graduates in the United States per academic year since 1905 are reported in table 21. The 6,389 graduates reported for this year are the most reported for any single academic year since the Council on Medical Education and Hospitals was established. It should be noted, however, that this number includes the students graduated during a thirteen month period in which ten schools graduated two classes. Three schools had more than 150 graduates in one class: Tennessee 173, Illinois 164 and Jefferson 151.

Seven schools graduated fewer than 50 students in one class: Alabama 21, Vermont 33, Utah 35, Woman's Medical 35, Syracuse 37, Bowman Gray 38 and Albany 43.

In Canada the most graduates were at Toronto, 124, and the fewest at Alberta, 21, and Dalhousie, 28.

Of the total of 6,956 graduates in the United States and Canada during 1946-1947, 62.8 per cent possessed a baccalaureate degree. The number and percentage of graduates with a baccalaureate degree from each medical school are shown in table 22.

Production of Physicians, 1937-1942 and 1942-1947

It is now possible to give a final figure for the total number of additional physicians produced as a consequence of wartime acceleration and increased enrolments in medical schools. In measuring this aspect of the war effort of medical schools the additional physicians who will be trained by the schools that are continuing to admit classes on an accelerated program in peacetime are not included.

In the five prewar years from July 1, 1937 to June 30, 1942, 25,818 physicians were graduated from the medical schools in the United States. In the five years from July 1, 1942 to June 30, 1947, 32,877 physicians have been graduated. The accelerated program thus made possible the training of 7,059 additional physicians, an increase of 27.3 per cent over the number of physicians trained during the five year period immediately preceding the adoption of the accelerated program.

in the United States in Additional Classes, 1946-1947

4	..	..	..	..	1	3	1	1	..	..	..	..	..	2	..	11	1	..	2	..	..	2	..	..	1	..	..	..	..	..	1	..	32	1	5	..	..	73	4
	60	0	0	0	1	5	100	30	2	3	1	0	0	4	0	13	2	1	10	1	0	5	0	0	2	1	0	0	0	0	3	2	32	2	7	0	0	307	
	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	32	33	34	35	36	37	38	39	40	41	42	43	44	45	46	47	48	49	50	51	52		

During the period July 1, 1937 to June 30, 1942, when 25,818 physicians were graduated, 18,988 physicians were reported to have died. Thus the net increase in the number of physicians for that five year period was 6,920. During the five year period July 1, 1942 to June 30, 1947, 32,877 physicians were graduated and 16,435 died, making a net increase of 16,442.

Required Internships

The medical schools requiring an internship for the degree of Doctor of Medicine are shown in table 23. There are six schools in the United States and four in Canada with this requirement. There has been no change in this list in the past four years. In the academic year 1946-1947 there were 582 students of schools in this country and 170 from Canadian schools in the required year of internship training or research. In table 12 is shown for each year since 1930-1931 the number of students from schools of the United States in the required intern year.

States requiring the internship for licensure are listed in table 24. There are twenty-three such states. In addition the District of Columbia, Alaska, Hawaii, Puerto Rico, the Canal Zone and the homeopathic boards of Arkansas and Connecticut require an internship for licensure.

The licensing boards listed in table 24 have returned to the prewar requirement of a one year internship but will continue to accept the nine month wartime internship. Several of the boards, however, require an additional three months of training in a military or civilian hospital.[1]

The licensing boards of Delaware, Hawaii, Illinois, Iowa, Michigan, New Jersey, North Dakota, Pennsylvania, Rhode Island, Utah, Washington and Wisconsin require the internship to be a rotating service.

Five states (Connecticut, Maryland, Missouri, Texas and Virginia) whose laws do not require internship withhold the licenses of candidates from schools requiring an internship for the degree of Doctor of Medicine until the internship is completed. In these states the examination may be taken at any time after completion of the medical school course.

Some states require an internship of graduates from schools abroad and applicants for reciprocity or endorsement.

* Does not include students in additional classes.

The hospitals approved for intern training by the Council on Medical Education and Hospitals of the American Medical Association (see pages 1323 to 1334, this issue) are generally acceptable in those states requiring an internship for licensure.

Premedical Training

The minimum requirement of the Council on Medical Education and Hospitals for admission to approved medical schools since 1918 has been two years of college training, and in 1938 three years was recommended. With the exception of California the state licensing boards, by statute in the majority of instances, require that an applicant for licensure must present evidence of having completed two years of college. The two year requirement became effective in Connecticut on July 1, 1947. In November 1942 the Council on Medical Education and Hospitals recommended that, for the duration of the war, premedical education, including satisfactory courses in physics, biology and inorganic and organic chemistry, be included within two calendar years. Such a program was adopted by practically all medical schools in the United States and Canada. There is a distinct trend toward the reestablishment of the prewar requirements. There are now seventy-five of the eighty-seven schools requiring three or more years of premedical work.

* Includes figures for schools of the basic medical sciences.
† Includes figures for additional classes.

An important problem regarding premedical requirements is posed by the many excellent educational opportunities at the high school and college level afforded men in the armed forces. The American Council on Education recommends the awarding of certain high school and college credits for courses taken by members of the armed forces (*a*) by correspondence through the "Armed Forces Institute," which operates in collaboration with colleges and universities, and (*b*) in classroom work in various schools operated for men and women in the armed services.

The American Council on Education, representing higher education in this country, has carefully evaluated the content and quality of the many courses given in both these categories. It has issued the "Guide to the Evaluation of Educational Experiences in the Armed Forces" to assist colleges desiring to do so to award ,

* Includes additional class.

proper high school and college credit for specific courses taken in this program.

In addition to awarding credit for courses actually taken, as already described, there is a program for evaluating a veteran's learning experiences while in the armed forces by administering "general educational development tests" and awarding appropriate credit at the high school and college levels on the basis of the examination results, even though formal course work in the subject matter of the examination was *not taken* by the candidate. These are comprehensive examinations developed by the Armed Forces Institute and sponsored by the American Council on Education.

The Council on Medical Education and Hospitals has agreed to these recommendations in principle in the following statement:

High School and College Credit for Veterans

A. Courses at the high school and college level have been offered to members of the armed forces,

1. by correspondence through the "Armed Forces Institute," which operates in collaboration with colleges and universities, and
2. in classroom work in various schools operated for men and women in the armed services.

The American Council on Education, representing higher education in this country, has carefully evaluated the content and quality of the many courses given in both these categories. It has issued the "Guide to the Evaluation of Educational Experiences in the Armed Forces" to assist colleges desiring to do so to award *proper high school and college credit for specific courses taken in this program.*

B. In addition to awarding credit for courses actually taken, as described in A, there is a program for evaluating a veteran's knowledge in a given field by administering "General Educational Development Tests" and awarding appropriate credit at the high school and college levels on the basis of the examination results, even though formal course work in the subject matter of the examination was not taken by the candidate. These are comprehensive examinations developed by the Armed Forces Institute and sponsored by the American Council on Education.

C. The Council on Medical Education and Hospitals of the American Medical Association (*a*) has confidence in the American Council on Education and its "Guide to the Evaluation of Educational Experiences in the Armed Forces," in the Armed Forces Institute and in the General Educational Development tests and (*b*) wishes to support sound procedures permitting veterans to commence their education in civilian institutions at a level commensurate with their ability and knowledge. Therefore the Council has decided that approved medical schools desiring to accept students at the freshman level partially on the basis of high school or college awarded credit as described in A and B will not be in conflict with the Council's regulations and policies, except that college credit for science courses requiring laboratory work should not be allowed on this basis, nor should blanket credit be allowed for military service not based on courses or examinations. Specifically, a medical college may accept, in partial fulfilment of premedical requirements:

1. High school credits, based on

(*a*) Courses taken from the Armed Forces Institute or in service courses of the armed forces according to the "Guide to the Evaluation of Educational Experiences in the Armed Forces."

(*b*) Performance in the General Educational Development Tests; such credit may include the equivalent of a complete high school course.

2. College credits (except in science courses requiring laboratory work, or except blanket credits for military services not based on courses or examinations), based on

(*a*) Courses taken from the Armed Forces Institute or in service courses of the armed forces according to the "Guide to the Evaluation of Educational Experiences in the Armed Forces."

(*b*) Performance in the General Education Development Tests.

The licensing boards of all but four states have indicated that the awarding of premedical credits under this plan by approved medical schools as the equivalent of the required premedical training will satisfy the requirement for licensure.

The Army Specialized Training and Navy V-12 premedical programs called for less than two years of college training, but in both these programs the studies were continuous and provided for the student carrying more than the normal peacetime studies per semester. Both the Army and Navy programs provided for work well in excess of the sixty semester hours constituting the normal two academic years of medical study. The information received from those states whose licensure laws include specific premedical requirements seems to indicate that there should be no licensure difficulties encountered by students whose premedical work was taken under the Army Specialized Training or Navy V-12 or comparably accelerated civilian programs.

The 1947 Freshman Class

By June of this year the medical schools and schools of the basic medical sciences in the United States had already selected 6,252 students for admission in 1947. This group is composed of 4,399 male veterans (70 per cent), 1,301 other men (21 per cent) and 598 women (9 per cent). Forty-seven of the women are veterans.

These preliminary figures indicate that next year's freshman enrolment in medical schools in this country will be close to the figure for the peak year, the 1944 "second session," when 6,648 freshmen were enrolled. It would also appear that there will be more veterans in the 1947 freshman class than in the present year and somewhat fewer women.

By June a number of schools had already admitted more freshman students than they had admitted in any one session during the war years. In ten schools present figures indicate that the freshman classes in 1947-1948 will be at least 10 per cent larger than those enrolled in 1941-1942. In one school the scheduled freshman enrolment for 1947-1948 already exceeds the 1941-1942 figure by 30 per cent.

It is appropriate to comment at this place that certain schools have strengthened their faculties and increased their physical facilities sufficiently to enable them to increase their enrolments above the prewar level without impairing the quality of instruction. Unfortunately such justification for expanded enrolments does not exist for all the schools that are admitting an increased number of freshmen.

Fees

The eighty-seven medical schools in the United States and Canada have been arranged in six groups in table 25 according to tuition fees charged resident students for the session 1946-1947. The figures are based on the average tuition fee charged for the complete medical course and include such minor charges as those for matriculation, breakage, diploma and graduation.

An upward trend in tuition fees is still continuing. The average tuition fee for an academic year charged by medical schools in the United States in the past seven years has increased from $378 in 1940 to $459 in 1947. However, this is an increase of 21 per cent, which is considerably less than the increase in the costs of most services and commodities during the same period.

Thirty-three schools in the United States and five in Canada make an additional charge for nonresidents. These sums vary considerably in amount. The lowest charge is at Toronto, where nonresidents in the freshman class pay $5 a year and nonresidents in other classes pay $10. The highest nonresident fees are at Oklahoma ($350) and Louisiana ($400).

The Financing of Medical Schools

The budgets of the medical and basic science schools in the United States for the academic year 1947-1948 total somewhat more than $43,000,000. In reporting the figures from which this sum was compiled, the medical schools excluded, with a few partial exceptions, the costs of patient care in their teaching hospitals. Research grants from foundations, governmental agencies and other outside sources were also excluded.

The figures from some medical schools incorporated allowances for general university administration and plant maintenance. Other schools did not include one or both of these items. The lack of uniformity in reporting these costs, however, does not detract significantly from the validity of the total figure as a close approximation of the cost of operating the medical schools of this country for the coming year.

One other correction must also be applied. Four schools had only their budgetary figures for 1946-1947 available and the most recent figures that one school could provide were those for 1945-1946. Again, it is believed that these corrections would not alter the total significantly.

Of the total of $43,000,000 that will be needed to operate the medical schools of this country in the coming year, students' fees will provide no more than $12,000,000 and probably somewhat less. The remaining $31,000,000 will be obtained from income from endowments, general university funds, appropriations from tax funds, gifts and similar sources. The fact that only 28 per cent or less of the total cost of undergraduate medical education next year will be met by student fees is impressive evidence for the frequently repeated statement that income from tuition provides but a small fraction of the financial support required by medical schools.

Because there is a fourfold variation in size between the smallest and the largest medical schools in this country, a meaningful comparison of budgets can be made only by determining the expenditures per student for each school. Employing the enrolment statistics for 1946-1947, the latest complete figures available, the range of expenditures per student planned by the medical and basic science schools in this country for 1947-1948 is found to extend from $600 to over $5,000.

In table 26 the seventy-seven medical and basic science schools in the United States have been arranged in eight groups according to their anticipated expenditures per student for 1947-1948.

[illegible]	1
Over 5,000	3
Total	77

1. 1946-1947 expenditure for one school; 1945-1946 expenditure for one school.

2. 1946-1947 expenditures for three schools.

The figures from many schools indicate that in recent years there has been an appreciable increase in the operating funds that have been secured over and above student fees. Five schools, however, are still unable to provide from nonstudent sources as much as fifty cents for every dollar of tuition collected. Twelve other schools cannot yet match student fees dollar for dollar. It would seem clear that the schools in these two groups must be furnished with more adequate financial support if they are to offer training comparable in quality to that provided in the majority of the medical schools of this country.

Present figures indicate that the medical schools of this country will receive about $10,000,000 in grants from foundations, government agencies and other sources during the coming year. Most of these grants are primarily for research projects, although some are being given for the express purpose of improving instructional programs.

There is a wide range in the sums that will be obtained in the form of grants by the different schools. Several schools do not anticipate receiving any grants. At the other extreme, one school is receiving grants totaling more than $750,000 and five other schools are receiving total grants of $500,000 or more. In addition to these schools, twenty-one others are receiving grants ranging from $100,000 to $490,000 for the next academic year.

Medical Schools Affiliated with Veterans Administration Hospitals

Fifty-five of the four year schools and one of the basic science schools in the United States are now affiliated with one or more Veterans Administration hospitals. One school is affiliated with a Veterans Administration clinic and four schools are prepared to affiliate as soon as hospitals which are to be constructed in their vicinity are in operation.

While there is some variation in the scope of activity carried on by the various medical schools and in the responsibilities which they have assumed, all the schools have undertaken to develop and supervise educational programs of high quality for the residents in the hospitals with which they have affiliated. This program has greatly increased the attractiveness of the residencies in these hospitals for able young physicians and in many other ways has directly and indirectly brought about remarkable improvements in the quality of patient care rendered in these institutions.

As of June 1947, forty-five of the participating medical schools stated without qualification that the affiliation was operating in a satisfactory manner. Seven other schools expressed satisfaction with the program, but with qualifications. Five schools did not express an opinion about the operation of the program.

Basic Science Training for Residents

Each specialty board requires that candidates for certification demonstrate a sound knowledge of the basic medical sciences as they apply to the given specialty. Certain boards recommend or require that the candidate's preparation for certification include time spent in a formal course of study in one or more of the basic medical sciences.

The basic science departments of fifty-eight of the seventy medical schools in this country now offer some form of organized training for the residents of their own or affiliated hospitals. In some schools such training is limited to one or two subjects; in others courses are offered in all, or almost all, the basic medical sciences.

Eleven medical schools provide organized basic science training only for the residents of their own hospitals, eight offer such courses only for affiliated hospitals and thirty-nine admit to their courses both the residents of their own hospitals and those of affiliated institutions, including Veterans Administration hospitals.

During the past year the desirability of having medical schools increase their efforts to provide formal basic science training for residents has been questioned on two grounds. It has been urged that the most valuable form of basic science training for physicians seeking to perfect themselves in the practice of one of the branches of medicine is that which stresses the clinical application of the basic medical sciences. The opinion is widely held that such training is provided more effectively in the wards and laboratories of the hospitals that are training residents than it is in the classrooms or laboratories of a medical school.

The other important objection that has been raised against the development by medical schools of formal courses for residents is that most medical schools do not have the personnel or the physical equipment to provide satisfactory training for residents without impairing the quality of their undergraduate instruction.

In view of the general lack of enthusiasm for providing such courses which the medical schools displayed earlier this year, it is somewhat surprising to find that fifty-eight schools are now furnishing this type of training. The experience of these schools over the next several years should provide valuable information for determining how much responsibility it is desirable and advisable for medical schools to assume in this phase of graduate training.

New Medical Schools

One new medical school, the University of Washington School of Medicine, opened in Seattle during the past year. This school, which is planning the development of a four year program, admitted its first freshman class in the fall of 1946. During the coming academic year the school will have both a freshman and a sophomore class enrolled.

The development of new medical schools is being actively considered in several other states. In last year's Educational Number it was mentioned that every school of the basic medical sciences except Dartmouth had expansion to the full four year status under consideration. In the interval Mississippi and South Dakota have abandoned, at least for the present, plans for immediate expansion. Expansion has been authorized by law in North Carolina, North Dakota and Missouri. A final decision has not yet been reached in West Virginia.

The University of California has been authorized to develop a four year medical school in Los Angeles. Funds have been appropriated to initiate a building program, and a dean has been appointed.

The Florida legislature has authorized the University of Florida to establish a medical school at Gainesville. The University of Miami is also contemplating the development of a school of medicine.

Other universities that are reported to be actively considering the creation of medical departments are Rutgers and the University of Connecticut. In several other states preliminary discussions have been initiated concerning the advisability and desirability of founding new medical schools.

It would seem clear that a gradual expansion of the facilities for medical education in this country will occur during the next several years. It is essential that this expansion be carefully planned with respect to the ability of the sponsoring agencies to establish and maintain medical schools that will provide training of unquestioned quality. In the field of higher education there is no undertaking more expensive than the establishment of an acceptable medical school. The expansion of opportunities for training in medicine should also be guided by the accurately determined quantitative needs of this country for physicians.

Survey of Medical Education

The last comprehensive survey of medical education in this country was that conducted by the Council on Medical Education and Hospitals during the period 1934-1936. The findings of this survey and supplementary studies were published in 1940 in what has come to be known as the "Weiskotten report." This report proved to be of great value in providing specific information concerning the status of medical education in this country. It also led to the prompt correction of many of the deficiencies that were brought to light.

The Board of Trustees of the American Medical Association has now authorized the Council on Medical Education and Hospitals to conduct another comprehensive survey of medical education in this country. The Council will be joined in this survey by the Association of American Medical Colleges. Representatives of these two organizations are now developing plans for a survey designed to provide current, reliable information which can serve as a basis for further improvements and advances in medical education in this country.

APPROVED INTERNSHIPS, RESIDENCIES AND FELLOWSHIPS

Revision of Residency Standards

The standards governing the approval of residencies in specialties have recently been revised by the Council on Medical Education and Hospitals in cooperation with the American specialty boards. These new Essentials of Approved Residencies and Fellowships were officially adopted by the House of Delegates of the American Medical Association at its centennial session in Atlantic City in June 1947. Under the present standards approval of residency training programs may be extended in the following classifications:

1. Allergy
2. Anesthesiology
3. Cardiovascular Disease
4. Contagious Diseases
5. Dermatology and Syphilology
6. Gastroenterology
7. General Residency
8. Internal Medicine
9. Malignant Diseases
10. Neurological Surgery
11. Neurology
12. Obstetrics and Gynecology
13. Occupational Medicine
14. Ophthalmology
15. Orthopedic Surgery
16. Otolaryngology
17. Pathology
18 Pediatrics
19. Physical Medicine
20. Plastic Surgery
21. Proctology
22. Psychiatry
23. Pulmonary Diseases
24. Radiology
25. Surgery
26. Thoracic Surgery
27. Urology

In comparison with the 1939 revision it will be noted that four new classifications have been added to the residency list, namely allergy, gastroenterology, occupational medicine and proctology. On the other hand, the separate listing of residencies in epilepsy, mental deficiencies and traumatic surgery has been discontinued. Training programs in epilepsy and mental deficiencies would now fall under the classification of psychiatry and neurology, whereas those in traumatic surgery have been transferred either to general surgery or to orthopedic surgery. There has also been a change in terminology in several fields, giving a clearer definition of the scope and type of training involved. Residencies in cardiology have been changed to cardiovascular disease, those in communicable diseases to contagious diseases, mixed residencies to general residencies, physical therapy to physical medicine and tuberculosis to pulmonary diseases.

As in the previous revision, the present standards describe the general requirements applicable to all types of residency training, the special requirements pertaining to individual specialties, resident-intern relationships, the recording of credit in the biographic files of the American Medical Association and the procedures involved in the evaluation and approval of residency training programs. All sections have been fully revised, however, giving a clearer definition of the general and special requirements in each field, quantitative requirements in relation to clinical material, applied basic science instruction and board requirements in those fields in which certifying boards have been organized. New regulations have been included in several divisions which were not fully described in the previous Essentials. Under general requirements a section on Teaching and Investigation has been added as well as a comprehensive statement clarifying the requirements in regard to basic science training. While it is pointed out that a resident seeking certification should be able to apply the basic sciences of anatomy, bacteriology, biochemistry, pathology, pharmacology and physiology to his special field, it is equally emphasized that "such training does not necessitate formal course work, specific assigned laboratory exercises or affiliation of the residency hospital with a medical school; it should be distinctly of an applied nature, closely integrated with the clinical experience of the resident."

The new Essentials of Approved Residencies and Fellowships, published elsewhere in this issue, will be reprinted and distributed to all approved hospitals, medical schools, specialty boards and other agencies concerned in the development and maintenance of educational services for resident physicians.

Residencies in Specialties

The number of approved residencies in civilian hospitals in the United States has increased by more than 100 per cent since 1941. The present total of 12,003 residencies as compared with 5,256 at the beginning of the war illustrates not only the tremendous expansion that has taken place in recent years but reflects also the generous cooperation and support of the large number of physicians, hospitals, medical schools and other agencies through whose efforts the development of additional residency training programs has been made possible. In 1941 the hospitals approved by the American Medical Association for the training of resident physicians totaled 610. This number has now increased to 1,017, including 9 hospitals of the Army, 16 of the Navy, 8 of the U. S. Public Health Service and 51

* Includes fellowships.

† Includes 18 residencies in allergy, 19 in cardiovascular disease, 70 in contagious diseases and 360 in pulmonary diseases.

‡ Includes 94 residencies in malignant diseases and 66 in thoracic surgery.

¶ Number of residency programs in 992 hospitals approved for residency training (residency programs in 9 Army and 16 Navy hospitals not included).

§ Total internships 8,539 plus 64 in Canal Zone, Hawaii and Puerto Rico.

a. Approximately 500 additional general residencies available in hospitals approved for intern training which are likewise accredited for general residencies.

b. Includes 316 residencies in opthalmology and 314 in otolaryngology.

of the Veterans Administration. Expansion of residency training programs has occurred in all specialties. On a percentage basis the greatest increase is in the fields of anesthesiology, neurologic surgery, physical medicine and plastic surgery, excluding in this connection the divisions of allergy and proctology, which were not represented in the previous classification. Numerically the specialty of internal medicine predominates, with a total of 2,677 residencies as compared with 1,126 in the prewar period. General surgery increased from 1,007 to 2,229, psychiatry and neurology from 497 to 1,470, obstetrics and gynecology from 442 to 961, pediatrics from 393 to 717, radiology from 250 to 638, ophthalmology and otolaryngology from 441 to 630, pathology from 332 to 617 and orthopedic surgery from 200 to 565. Included in internal medicine are 18 residencies in allergy, 19 in cardiovascular disease, 70 in contagious diseases and 360 in pulmonary diseases, formerly classified as tuberculosis. Grouped with general surgery, on the other hand, are 66 residencies in thoracic surgery and 94 in malignant diseases. Neurology has 173 residencies, psychiatry 1,297.

While residency training is centered mainly in the specialty fields, it should be noted that many of the hospitals approved by the Council have established educational programs designed primarily to provide additional experience in preparation for general practice. These services, which are similar to second year rotating internships, are ordinarily classified as general or mixed residencies. At present 94 hospitals hold separate approval for general residency training and can accommodate 296 applicants. In addition, nearly 500 general residencies are available in the approved internship hospitals, all of which are likewise accredited for general residency training. The organization and maintenance of residencies of this type are an important development in providing opportunities for the training of physicians planning to practice general medicine. This is also in keeping with the development of general practice sections in hospitals as recommended by the Council on Medical Education and Hospitals of the American Medical Association.

Reference should be made to the accompanying table showing the number and classification of residencies now provided in 992 approved hospitals, excluding, however, the residency training programs of the Army and Navy. Comparative data have also been included on the number of residencies available in 1941. The hospitals of the Army, Navy, U. S. Public Health Service and Veterans Administration are taking an active part in the program of residency training and can accommodate over 2,000 resident physicians, as described in The Journal, April 12, 1947. These institutions are making steady progress in the development and organization of educational services, a large number of which have already received Council approval. Elsewhere in this issue is a full list of the residency training programs currently approved by the American Medical Association.

Approved Hospital Internships

The list of approved internships published in this issue of The Journal shows that there are within the continental limits of the United States 764 civilian hospitals approved by the American Medical Association for the training of interns. These institutions can accommodate 8,539 interns, as compared with an average yearly total of approximately 5,500 medical graduates. On direct comparison of the number of internships and senior medical students it would seem that the facilities for intern training greatly exceed the required need. It is found on closer study, however, that the size of the graduating class ordinarily does not determine the number of interns engaged in hospital training. In 1939, for example, when 7,765 internships were available, the approved hospitals employed 7,448 interns as compared with 5,089 medical graduates. A similar observation in 1940 gives further indication that under normal conditions a reserve supply of over 2,000 internships may be necessary to meet the needs of those who desire an additional year of general hospital experience.

In the possessions and territories of the United States there are 8 approved internship hospitals: 1 in the Canal Zone, 3 in Hawaii and 4 in Puerto Rico. These have facilities for the training of 64 interns. The Navy, which is training approximately 120 interns, is concentrating its educational service in 20 general hospitals approved by the Council. The Army has reestablished its intern training program and will accommodate approximately 100 interns in 8 Army general hospitals approved by the American Medical Association. The U. S. Public Health Service has facilities for 120 interns in 10 Marine hospitals.

The hospital internships have now returned to a peacetime status, maintaining as a general rule a minimum assignment of one year in accordance with the usual July to July schedule. A further extension of the internship to two years is under consideration in several hospitals in order that interns may obtain wider and more adequate experience in the general preparation for medical practice. The uniform plan for the appointment of interns is described in The Journal, April 12, 1947.

POSTGRADUATE COURSES FOR VETERAN AND CIVILIAN PHYSICIANS

An important aid to the physician desiring to keep abreast of the progress of medicine is the offering of continuation courses throughout the country. Since 1937 the Council on Medical Education and Hospitals has collected and published periodically lists of courses of a review and refresher nature. These listings include courses in a wide variety of fields in clinical medicine and in the basic sciences. The courses are for variable periods from a few days to several months. Some are concentrated full time courses and others are part time. In the June 14 and June 21 issues of The Journal more than eight hundred courses offered by numerous institutions and organizations are listed covering the period from July 1, 1947 to Jan. 15, 1948. The medical schools take a prominent part in presenting these courses. In addition, other agencies offering courses employ the facilities of the medical schools. The institutions and individuals participating in these programs are rendering a great service to the profession and to the physician veterans. Institutions offering this type of training are invited to announce such courses in these semiannual lists compiled by the Council.

These continuation or review courses do not ordinarily provide credit of any kind, as the courses are not designed to prepare men for board certification. Some opportunities are offered for review work in preparation for examinations in the specialties as given by the boards. They are applicable to the educational benefits provided physician veterans under the G. I. Bill of Rights.

In the following paragraphs mention is made of some of the recent and noteworthy developments in postgraduate education. An analysis of the courses offered during the period July 1, 1946 to July 1, 1947 is also presented.

Recent Developments

The Chicago Medical Society is expanding its services and plans to offer postgraduate courses open to physicians of the country. Two courses, one in cardiovascular diseases and another in gastroenterology, have already been scheduled.

The Illinois State Medical Society sponsors one day conferences in all parts of the state. They are arranged at the request of the secretary of the county medical society. These may consist of round table conferences and clinics in addition to speakers

The Department of Otolaryngology of the College of Medicine of the State University of Iowa has announced the presentation of a five day intensive course covering the specialties of otology, rhinology and laryngology.

The program of postgraduate instruction in Kansas is a joint undertaking of the state board of health, the state medical society and the University of Kansas School of Medicine

Tulane University School of Medicine offered a course of one week full time in obstetrics and gynecology designed for Latin American physicians.

The Mississippi State Board of Health will offer scholarships for courses in maternal and child health at Tulane University

The affiliation of the New York Post-Graduate Medical School and the New York Eye and Ear Infirmary with Columbia University has been discontinued During the year 1946-1947 the New York Post-Graduate School enrolled a total of 1,119 physicians, of whom 615 were physician veterans. Physicians were enrolled from forty-four states, the District of Columbia, two of the territories and thirty-six foreign countries This was the third largest enrolment in the school's history.

The county medical societies of New York State regularly schedule postgraduate lectures This instruction is presented as a cooperative endeavor between the medical society of the state and the state department of health.

The Medical Society of the State of Pennsylvania will, beginning Oct 7, 1947, inaugurate a program consisting of eight hours of didactic instruction one day a week for five weeks given by teachers from the various medical schools of the state This will be a continuous course for three years, offered twice a year. The forthcoming course will be offered in six towns, and four subjects are scheduled.

Meharry Medical College offers courses for Negro physicians

The American Academy of Ophthalmology and Otolaryngology offers home study courses through nine months corresponding to the school year Reading assignments are mailed each month followed by questions sent four weeks later The courses are of a basic nature and are usually taken by residents

Postgraduate Medicine, a monthly journal, was published beginning January 1947 by the Interstate Postgraduate Medical Association of North America. Much of the basic material consists of addresses presented at the annual meeting of this association, but it is expected that new material will be supplemented, originating in various postgraduate centers.

Analysis of Courses Offered in 1946-1947

In presenting this analysis of postgraduate courses which have been offered during the annual period July 1, 1946 to July 1, 1947 the statistical summaries are divided into three groups: short review courses, courses of more than five days' duration and, lastly, a group including clinical conferences, graduate assemblies, study courses and courses of a chautauqua nature.

Short Review Courses—Twenty-five states and the District of Columbia provided opportunities of less than five days' duration for physicians to continue professional study in or near their home communities These twenty-five states and the District of Columbia offered 239 courses as follows:

Alabama	2	Massachusetts	5	Oklahoma	10
California	26	Michigan	11	Oregon	1
Colorado	7	Minnesota	13	Pennsylvania	5
Connecticut	2	Missouri	1	South Carolina	2
District Columbia	1	Nebraska	1	Tennessee	1
Illinois	9	New Jersey	5	Texas	12
Iowa	4	New York	89	Virginia	4
Kansas	17	North Carolina	2	Wisconsin	5
Kentucky	2	Ohio	2		—
Totals					239

The subjects of these courses of less than five days' duration included:

Allergy
Anesthesiology
Arthritis
Biochemistry
Cardiovascular disease
Chest diseases
Dermatology and syphilology
Diabetes
Electrocardiography
Electroencephalography
Endocrinology
Endoscopy
Fractures
Gastroenterology
Hematology
Industrial health
Legal medicine
Malignant diseases
Medicine, general
Neurology and psychiatry
Obstetrics and gynecology
Ophthalmology
Orthopedic surgery
Otolaryngology
Otology
Pathology
Pediatrics
Physical medicine
Physiology
Proctology
Public health
Radiology
Surgery, general
Therapy
Urology
Venereal diseases

The courses varied in length from one session of one and one-half hours to five days' full time and consisted of organized courses, daily set clinics on patients in the wards and evening lectures, with emphasis on recent developments. The type of instruction was didactic, clinical or both The instructors were chosen from physicians practicing in the state in which the courses were offered as well as from out of state. Medical school faculties participated in 150 courses. The facilities used included hospitals, clinics, medical schools and hotels

These offerings were held in every month but August, the majority being given in January, April, September and October, while in 21 instances they were arranged at the convenience of the applicant. Thirty-seven courses were available for specialists only. Fees ranged from $3 to $200, the majority under $50. In 37 instances no fee was charged

The attendance reported for 205 courses was 16,274, while 34 did not indicate enrolment figures.

The value of this type of instruction to the busy practitioner is becoming more popular, since it enables him to obtain information regarding newer technics in medical practice without the necessity of prolonged absence from his practice.

Courses of More Than Five Days.—In centers where ample clinical facilities are available, 1,291 graduate courses of more than five days' duration were offered in thirty-one states and the District of Columbia during 1946-1947. These states and the number of courses which were given in each state are as follows:

Alabama	4	Louisiana	26	North Carolina	56
California	52	Maine	2	Ohio	7
Colorado	1	Maryland	13	Oregon	17
Connecticut	1	Massachusetts	59	Pennsylvania	56
District Columbia	52	Michigan	104	Tennessee	19
Florida	1	Minnesota	25	Texas	14
Georgia	10	Mississippi	3	Vermont	7
Illinois	176	Missouri	10	Virginia	10
Iowa	18	Nebraska	9	Washington	3
Kansas	10	New Jersey	7	Wisconsin	15
Kentucky	3	New York	501		
Totals					1,291

These courses, consisting of refresher courses of five or more days to intensive courses extending over one year and in 3 instances to three years, were offered in both the basic sciences and clinical subjects. Forty-six subjects were covered. While the majority of the courses were in various subjects, specific courses in general medicine were offered in 193 instances, surgery in 125, neurology and psychiatry in 101, obstetrics and gynecology in 104, ophthalmology in 92, pediatrics in 62, dermatology and syphilology in 45 and anatomy in 40. Fewer than five courses were given in 9 subjects.

The length of these courses varied from five days to one month for 517 courses. There were offered 307 courses ranging in length from one to four months and 69 from five to twelve months. There were 18 one year courses and 3 given for three years, while the remainder specified the length of the course in hours, sessions, seminars, semesters or quarters.

The description of these intensive courses indicated that instruction was both clinical and didactic. Instruction was both didactic and clinical for 668 courses, didactic only for 90 and clinical only for 126. The remainder did not specify the type of instruction.

In presenting these courses, medical school facilities were used for 783 courses, hospitals for 752 and clinics for 495. In many instances two or all three of these sources were used in presenting an individual course. Hotel and other facilities were used for 42 courses. One course was a home study course.

The faculties of medical schools served as instructors in 757 courses. Additional instructors were specialists in their field, chosen mainly (in 474 instances) from physicians residing within the state in which the course was given but including as well physicians from outside the state.

Courses were offered during every month last year, and in 206 instances they were arranged to suit the convenience of physician-students. There were 115 courses available for specialists only. Fees varied considerably, ranging from $1 to $1,000. In 53 instances no fee was charged.

The attendance reported for 1,137 of the 1,291 courses given in 1946-1947 was 23,062.

Sponsoring and Contributing Agencies.—One hundred and thirty-five agencies participated in the sponsoring of both the short review courses and the longer courses. These included 52 medical schools, 35 special societies, 16 hospitals, 14 state societies, 8 graduate schools, 6 county societies, 2 state health departments and 2 universities.

Twenty-one agencies, while not responsible for the development of these opportunities, were reported as contributing agencies. Grouped under special societies in addition to the national society in a given specialty are such agencies as the W. W. Kellogg Foundation, Commonwealth Fund, National Cancer Institute, Foundation for Vision and National Foundation for Infantile Paralysis.

Clinical Conferences, Graduate Assemblies, Study Courses, Chautauqua Courses.—In eleven states clinical conferences, graduate assemblies and study courses were held during 1946-1947. These opportunities varied in length from two sessions to two weeks, with the four day program being most common. Fourteen such meetings were conducted in these states. The majority surveyed topics in general medicine and surgery. Other subjects covered were cardiovascular disease, poliomyelitis, radiology, tumors and venereal diseases. In most instances the instruction was both didactic and clinical. The facilities of hospitals, clinics and medical schools were used. For this type of instruction a small registration fee was charged. The attendance numbered 17,914.

Table 28.—*Courses Offered and Attendance*

	1945-1946			1946-1947		
	Total Courses	Number Reporting Attendance	Attendance	Total Courses	Number Reporting Attendance	Attendance
Short review courses (five days or less)	154	128	4,140	239	205	16,274
Courses of less than a year and more than 5 days	1,070	1,043	19,991	1,291	1,137	23,062
Clinical conferences, graduate assemblies, study and chautauqua courses	52	52	21,824	21	21	20,475
Totals	1,276	1,223	45,955	1,551	1,363	59,811

In seven states (Arkansas, Massachusetts, Michigan, Nebraska, Oklahoma, Tennessee and Wisconsin) identical courses were offered in various centers throughout the state, ranging from three to twenty-five centers. Contributing agencies were medical schools, state medical societies, state health departments and private agencies. Instruction was both clinical and didactic Afternoons and evenings were most commonly employed by the instructors in presenting their subject. Last year this type of continuation training was offered in general medicine, cancer, gynecology, industrial health and psychiatry. No fee was larger than $10. The reported attendance was 2,561.

Summary.—In 33 states and the District of Columbia some form of continuation study for practicing physicians was provided during 1946-1947. Table 28 summarizes the recorded enrolment for the year 1946-1947, with comparative figures for the previous year. The popularity of this type of training is evidenced in the total figure (59,811), which represents the greatest number of physicians to seek such opportunities in a single year. In 1944-1945 the attendance totaled 18,206, and in 1945-1946 it was 45,955.

The institutions of the country are to be commended for the expansion of their facilities in order to provide this form of continuation study for physicians.

APPROVED INTERNSHIPS

Council on Medical Education and Hospitals of the American Medical Association

535 North Dearborn Street, Chicago 10

Revised to Aug. 16, 1947

HOSPITALS, 764. INTERNSHIPS, 8,539

The following general hospitals, investigated and approved by the Council on Medical Education and Hospitals, are considered in position to furnish acceptable intern training in accordance with standards adopted by the American Medical Association. Three types of internships are approved by the Council—rotating, mixed and straight:

1. A rotating internship is defined as one which provides supervised experience in internal medicine, surgery, pediatrics, obstetrics and their related subspecialties, together with experience in laboratory and radiologic diagnosis. 2. A mixed internship is defined as one which provides supervised experience in two or more, but not in all, of the clinical divisions named. 3. A straight internship is defined as one which provides supervised experience in a single department, although it may include limited opportunity for work in a related subspecialty. Straight internships are now approved in internal medicine, surgery, pediatrics, obstetrics (with or without gynecology) and pathology.

The hospitals approved for intern training are likewise accredited for general residencies which represent general house staff assignments following the internship. The plus (+) sign indicates additional approval for residencies in specialties, as shown in the Council's list of Approved Residencies and Fellowships for Veteran and Civilian Physicians. Hospitals have now returned to the regular internships of 12 months duration or longer, appointments beginning as a general rule on July 1.

United States Army.

HOSPITALS APPROVED FOR INTERNSHIPS IN THE DOMINION OF CANADA

For the benefit of graduates of approved medical colleges who desire an internship in Canada, the Council on Medical Education and Hospitals of the American Medical Association has declared that hospitals which conform to the standards of the Canadian Medical Association should be regarded as giving an internship equivalent in educational value to that offered by hospitals in the United States approved for intern training by the Council. It is understood, however, that this statement applies only to hospitals that are unqualifiedly "Approved" under the Canadian plan and does not apply to that group referred to as "Commended."

The following list of hospitals, revised to April 1, 1947, has been furnished by the Canadian Medical Association.

Name of Hospital	Location
Camp Hill Hospital	Halifax, N. S.
Victoria General Hospital	Halifax, N. S.
St. John General Hospital	St. John, N. B.
Hospital du St. Sacrament	Quebec, Que.
Hospital Dieu de Quebec	Quebec, Que.
Hospital of the Infant Jesus	Quebec, Que.
Jeffrey Hale's Hospital	Quebec, Que.
Children's Memorial Hospital	Montreal, Que.
Herbert Reddy Mem. Hospital	Montreal, Que.
Homeopathic Hospital	Montreal, Que.
Hospital Notre Dame	Montreal, Que.
Hospital Ste. Jeanne d'Arc	Montreal, Que.
Hospital Ste. Justine	Montreal, Que.
Hotel Dieu de Montreal	Montreal, Que.
Hospital Ste. Luc	Montreal, Que.
Jewish General Hospital	Montreal, Que.
Montreal General Hospital	Montreal, Que.
Queen Mary Veterans Hospital	Montreal, Que.
Royal Victoria Hospital	Montreal, Que.
St. Mary's Hospital	Montreal, Que.
Ste. Anne's Hospital	Ste. Anne de Bellevue, Que.
Brantford General Hospital	Brantford, Ont.

Name of Hospital	Location
Hamilton General Hospital	Hamilton, Ont.
St. Joseph's Hospital	Hamilton, Ont.
St. Joseph's Hospital	London, Ont.
Victoria Hospital	London, Ont.
Westminster Hospital	London, Ont.
Oshawa General Hospital	Oshawa, Ont.
Ottawa Civic Hospital	Ottawa, Ont.
Ottawa General Hospital	Ottawa, Ont.
Hotel Dieu Hospital	Kingston, Ont.
Kingston General Hospital	Kingston, Ont.
Christie Street Hospital	Toronto, Ont.
Hospital for Sick Children	Toronto, Ont.
Mount Sinai Hospital	Toronto, Ont.
St. Joseph's Hospital	Toronto, Ont.
St. Michael's Hospital	Toronto, Ont.
Toronto East General Hospital	Toronto, Ont.
Toronto General Hospital	Toronto, Ont.
Toronto Western Hospital	Toronto, Ont.
Wellesley Hospital	Toronto, Ont.
Women's College Hospital	Toronto, Ont.
Grace Hospital	Windsor, Ont.
Metropolitan Hospital	Windsor, Ont.

Name of Hospital	Location
Hotel Dieu of St. Joseph	Windsor, Ont.
Children's Hospital	Winnipeg, Man.
Deer Lodge Hospital	Winnipeg, Man.
Misericordia Hospital	Winnipeg, Man.
Winnipeg General Hospital	Winnipeg, Man.
St. Boniface Hospital	St. Boniface, Man.
Regina Grey Nuns' Hospital	Regina, Sask.
Regina General Hospital	Regina, Sask.
St. Paul's Hospital	Saskatoon, Sask.
Saskatoon City Hospital	Saskatoon, Sask.
Calgary General Hospital	Calgary, Alta.
Colonel Belcher Hospital	Calgary, Alta.
Holy Cross Hospital	Calgary, Alta.
Edmonton General Hospital	Edmonton, Alta.
Misericordia Hospital	Edmonton, Alta.
Royal Alexandra Hospital	Edmonton, Alta.
University of Alberta Hosp.	Edmonton, Alta.

110 St. Michael Hospital, Milwaukee, outpatient service.
111 Kauikeolani Children's Hospital, Honolulu, pediatrics; Kalaupapa Settlement, Kalaupapa, leprosy.

APPROVED RESIDENCIES AND FELLOWSHIPS FOR VETERAN AND CIVILIAN PHYSICIANS

Council on Medical Education and Hospitals of the American Medical Association
535 North Dearborn Street, Chicago 10

Revised to August 16, 1947

Hospitals, 1,017; Assistant Residencies, Residencies and Fellowships, 12,003

The following educational services investigated and approved by the Council on Medical Education and Hospitals are considered in position to furnish acceptable residency training in accordance with standards adopted by the American Medical Association. In practically all fields these training programs have been reviewed in collaboration with the respective specialty boards. Included in the present list is the expanded number of residencies now available in those approved hospitals which have completed their plans to provide further opportunities for discharged medical officers. Many additional residencies recently organized or in process of development may soon be added to the approved list. All arrangements for appointments should be made directly with the hospital concerned in the usual manner.

The star (*) indicates hospitals that are also approved for the training of interns. All hospitals on the approved intern list are likewise accredited for general residencies which represent general house staff assignments following the internship.

The dagger (†) represents temporary approval, *pending formal inspection,* in accordance with the plan for the temporary approval of residencies in specialties as announced in The Journal A. M. A., March 2, 1946, p. 586.

6. GASTROENTEROLOGY

Approval of residencies in Gastroenterology has been authorized by the American Medical Association. Hospitals desiring residency approval in this field should make application to the Council on Medical Education and Hospitals, 535 N. Dearborn Street, Chicago 10, Illinois.

7. GENERAL RESIDENCY

A general residency (also called a "mixed residency") is a general hospital assignment of one or more years after the internship. It usually does not carry credit toward certification by the American Boards in the specialties, but is designed rather to provide additional general training. All approved internship hospitals are also approved for general residencies.

Hospitals, 140: Assistant Residencies and Residencies, 317

Mayo Foundation Fellowships—The Mayo Foundation for Medical Education and Research, Rochester, Minn.; three-year fellowships, beginning quarterly, leading to the degree of M.S or Ph.D. with field named from the University of Minnesota; in Anesthesia, Dermatology and Syphilology, Internal Medicine, Neurology and Psychiatry, Neurological Surgery, Obstetrics and Gynecology, Ophthalmology, Orthopedic Surgery, Otolaryngology, Pathology, Pediatrics, Physical Medicine, Plastic Surgery, Proctology, Radiology, Surgery, Urology; stipend $1,110 per year, (clinical fellowships including pathology and radiology—tentative estimate, 400). Address applications to The Mayo Foundation, Rochester, Minn.

---

a. Compensation arranged by medical school and hospital.
b. As reported in previous list.
c. In lieu of maintenance.
d. Residency in epilepsy.
e. Obstetrical training at Herman Kiefer Hospital, Detroit.
f. Training in gynecology at City of Detroit Receiving Hospital.
g. Assignment in psychosomatic medicine also available.
h. Fellowship offered in affiliation with Northwestern University Medical School, St. Luke's Hospital and Wesley Memorial Hospital, Chicago.
j. Outpatient and home delivery service only.
k. Training in gynecology at Barnes Hospital, St. Louis.
m. In affiliation with Cincinnati General Hospital.
½. Approved by the Board as offering satisfactory six months training.
1. Approved by the Board as offering satisfactory one year training.
1½. Approved by the Board as offering satisfactory eighteen months training.
2. Approved by the Board as offering satisfactory two year training.
2½. Approved by the Board as offering satisfactory thirty months training.
3. Approved by the Board as offering satisfactory three year training.
4. Residencies open to women.
5. Clinical data includes psychiatry.
6. Inpatients: Data refers to total inpatients treated in specialty. Obstetrical admissions do not include newborn. In anesthesiology, general residency and pathology total hospital admissions are used.
7. Clinical data includes neurology.
8. Includes fellowships.
9. Affiliated with Northwest Clinic, Minot.
10. Includes acceptable affiliate assignment at Urologic Clinic, Philadelphia.
11. Includes affiliate service at South Bend Medical Laboratory, St. Joseph Hospital, South Bend; Elkhart General Hospital, Elkhart and St. Joseph's Hospital, Mishawaka, Indiana.
12. Represents training acceptable to Board in (1) radiology, (2) roentgenology, (3) therapeutic radiology, (4) diagnostic roentgenology.
13. Affiliated with North Carolina Orthopedic Hospital, Gastonia.
14. Type of training acceptable to Board: A—adult orthopedics; C—children's orthopedics; F—fractures; S—basic sciences.
15. Includes affiliate service at Emory University.
16. Includes assignment at Pima County General Hospital, Tucson.
17. Acceptable affiliations at Norton Memorial Infirmary and Veterans Administration Hospital, Louisville.
18. Included in the affiliated program of the University of Colorado Medical School.
19. Training will also be carried out at DeKalb Public Hospital and St. Mary's Hospital, DeKalb, Ill.
20. Part of three year program offered by Harper, City of Detroit Receiving and Children's Hospitals in affiliation with Wayne University.
21. In affiliation with Johns Hopkins Hospital, Baltimore.
22. Approved for training in syphilology only.
23. Affiliated with Medical School of the University of Vermont, to include assignment at Bishop De Goesbriand Hospital.
24. Affiliated with Free Hospital for Women, Brookline, Mass.
25. In affiliation with Hartford Hospital, Hartford, Conn.
26. In affiliation with Good Samaritan and St. Vincent's Hospitals, Portland.
† Indicates temporary approval.

APPROVED MEDICAL SCHOOLS

ALABAMA

Birmingham

Medical College of Alabama.—Established in 1943 as a division of the University of Alabama. Located in Birmingham in 1944. In 1945 assumed title to Jefferson Hospital and Hillman Hospital, Birmingham. The Medical College of Alabama cares for all indigent patients of the county and city, maintenance of which is paid to the university on a per diem basis by the county. In 1943 appropriation included one million dollars for the building of a new medical school which will be erected as early as possible, and temporary quarters are now in the Jefferson-Hillman Hospital. First instruction in the Medical College of Alabama started June 4, 1945, with a junior class and this class was graduated in October, 1946. On October 8, 1945, the School of the Basic Medical Sciences on the University Campus, established in 1920, and its faculty, was absorbed into the new Medical College of Alabama. The medical college is coeducational. Minimum entrance requirements are three years of college work. The accelerated program started June 8, 1942, and discontinued in 1945 with the first freshman class. Tuition is as follows: for legal residents of Alabama $400 per academic year plus incidental fees of $20. Nonresidents of the state are charged an additional $100 each session. The registration for the 1946-1947 session was 157; graduates 21. The last class began for freshmen and sophomores Oct. 7, 1946, and ended June 10, 1947; for juniors Feb. 25, 1946 and ended in October, 1946. The last senior class began Oct. 21, 1946, and ended June 10, 1947. The next freshman session will start Oct. 6, 1947 and will end June 12, 1948. The Dean is Roy R. Kracke, M.D.

ARKANSAS

Little Rock

University of Arkansas School of Medicine, 1209 McAlmont Street.—Organized in 1879 as the Medical Department of Arkansas Industrial University. Present title in 1899. In 1911 the College of Physicians and Surgeons united with it and it became an integral part of the University of Arkansas. The first class was graduated in 1880. Clinical teaching was suspended in 1918 but resumed in 1923. Coeducational since organization. The curriculum covers four sessions of nine months each. At the present time entrance requirements are two years of collegiate work, but three years will be required beginning September, 1948. The B.S. degree is conferred at the end of the second year. An accelerated program, adopted July 1, 1943, involving the admittance and graduation of a class approximately every nine months, was discontinued July 1, 1946. The fees for the four years for residents of Arkansas are $280 a year; nonresidents are charged $225 additional each year. The registration for the 1946-1947 session was 248; graduates 47. The last session began September 30, 1946, and ended June 23, 1947. The next session will begin September 29, 1947, and will end June 21, 1948. The Dean is Benjamin B. Wells, M.D.

CALIFORNIA

Berkeley-San Francisco

University of California Medical School, University Campus, Berkeley; Medical Center, San Francisco 22.—Organized in 1864 as the Toland Medical College. The first class graduated in 1864. In 1873 it became the Medical Department of the University of California. In 1909, by legislative enactment, the College of Medicine of the University of Southern California, at Los Angeles, became a clinical department but was changed to a graduate school in 1914. In 1915 the Hahnemann Medical College of the Pacific was merged and elective chairs in homeopathic materia medica and therapeutics were provided. Coeducational since organization. Three years of collegiate work are required for admission. The work of the first year is given at Berkeley and that of the last three years at San Francisco. The medical course consists of four academic years, each containing two semesters of sixteen weeks each. The fees average $315 per academic year. Nonresidents are charged $250 additional each year. An accelerated program was adopted June 15, 1942 and discontinued in July 1946. The registration for the 1946-1947 session was 284; graduates 68. The last session began Sept. 19, 1946 and ended June 21, 1947. The next class will begin Sept. 18, 1947 and will end June 19, 1948. The Dean is Francis Scott Smyth, M.D., San Francisco.

Loma Linda-Los Angeles

College of Medical Evangelists, Loma Linda; Boyle and Michigan Avenues, Los Angeles 33.—Organized in 1909. The first class graduated in 1914. The laboratory departments are at Loma Linda; the clinical departments at Los Angeles. Coeducational since organization. Three years of collegiate work are required for admission. The freshman, sophomore and junior years consist of a nine month academic session and the senior year will have in addition to the nine month session a six weeks' clinical clerkship during the summer between the junior and senior years. A twelve month internship in an approved hospital is required. An accelerated program was adopted July 1, 1942 and discontinued June 30, 1946. The yearly tuitions including fees are respectively, $705, $694, $712, and $720. The registration for 1946-1947 was 324; graduates 90. The last session the freshman, sophomore and junior students began on September 22, 1946 and ended June 30, June 30, and June 20, 1947 respectively. The senior session began July 1, 1946 and was completed June 22, 1947. The next session will begin September 21, 1947 and will end on June 30, 1948 for the freshmen, June 20, 1948 for the sophomores, June 11 and 13 respectively for the juniors and seniors. The president is Walter E. Macpherson, M.D., Los Angeles. The deans are Harold Shryock, M.D., Loma Linda, and W. F. Norwood, Ph.D., Los Angeles.

Los Angeles

University of Southern California School of Medicine, 3551 University Avenue, Zone 7.—Organized in 1895 as the University of Southern California College of Medicine. First class graduated in 1888. In 1908 it became the Los Angeles Medical Department of the University of California. In 1909 the College of Physicians and Surgeons, established in 1904, became the Medical Department of the University of Southern California. Its activities were suspended in 1920; reorganized in May 1928, under present title. Entrance requirements are approximately 90 semester hours. An internship is required for graduation. Coeducational since organization. Annual fees amount to approximately $600. An accelerated program was adopted June 15, 1942 and discontinued September 16, 1946. The registration for 1946-1947 was 256; graduates 66. The last session began September 16, 1946 and ended June 14, 1947. The next session will begin September 15, 1947 and will end June 12, 1948. The Dean is Burrell O. Raulston, M.D.

Stanford University-San Francisco

Stanford University School of Medicine, University Campus, Stanford University; 2398 Sacramento Street, San Francisco. The main buildings are in San Francisco. The laboratories of anatomy, bacteriology and experimental pathology, chemistry, and physiology are located on the campus at Stanford University, which is thirty miles southeast of San Francisco adjoining the City of Palo Alto. The post office is Stanford University. Organized in 1908, when by agreement the interests of Cooper Medical College were taken over. The first class graduated in 1913. Coeducational since organization. Three years of collegiate work are required for admission. The quarter plan is in operation. An internship is a requirement for graduation. An accelerated program was adopted June 7, 1942 and discontinued June 29, 1946. The average fee for each of the four years is $600. The registration for 1946-1947 was 240; graduates 60. The last session for all classes began Sept. 23, 1946 and ended June 11, 1947. The next session will begin Sept. 29, 1947 and will end June 9, 1948. The Dean is Loren Roscoe Chandler, M.D.

COLORADO

Denver

University of Colorado School of Medicine, 4200 East Ninth Avenue.—Organized in 1883. Classes were graduated in 1885 and in all subsequent years except 1898 and 1899. Denver and Gross College of Medicine was merged Jan. 1, 1911. Coeducational since organization. The accelerated program was adopted June 15, 1942 and discontinued September 1946. The entrance requirements are three years of collegiate work. The fees average $283 per academic year. Nonresidents are charged $225 additional each year. The registration for 1946-1947 was 241; graduates 55. The last session began September 30, 1946 and ended June 9, 1947. The next session will begin October 6, 1947 and will end June 14, 1948. The Dean is Ward Darley, M.D.

CONNECTICUT

New Haven

Yale University School of Medicine, 333 Cedar Street.—Chartered in 1810 as the Medical Institution of Yale College. Organized in 1812; instruction began in 1813; first class graduated in 1814. A new charter in 1879 changed the name to the Medical Department of Yale College. In 1884, the Connecticut Medical Society surrendered such authority as had been granted by the first charter. In 1887, Yale College became Yale University. Coeducational since 1916. The requirements for admission are three years collegiate work. An accelerated program was adopted June 29, 1942 and discontinued March 28, 1946. The fees average $756 per academic year. The registration for 1946-1947 was 226; graduates 63. The last session for freshmen and sophomores began Sept. 16, 1946 and ended June 11, 1947; the last session for juniors and seniors began Mar. 28, 1946 and ended June 11, 1947. The next session will commence Sept. 22, 1947 and will end June 18, 1948. The Dean is C. N. H. Long, M.D.

DISTRICT OF COLUMBIA

Washington

Georgetown University School of Medicine, 3900 Reservoir Road, N. W., Zone 7.—Organized in 1851. First class graduated in 1852. The degree of Bachelor of Arts or Bachelor of Science or its equivalent from an approved college of arts and sciences is required for admission of non-veterans, but veterans may be admitted with a minimum of 90 semester hours of credit. The fees average $635 per academic year. Registration for 1946-1947 was 366, graduates 89. An accelerated program was adopted June 29, 1942 and discontinued March 17, 1946. The last session for freshmen began Sept. 16, 1946 and ended May 29, 1947; the sophomore class began Sept. 16, 1946 and ended May 26, 1947; the junior class began Sept. 16, 1946 and ended June 11, 1947 and the senior class began Sept. 16, 1946 and ended June 9, 1947. The next session will begin Sept. 22, 1947 and will end May 29, 1948. The Dean is Rev. Paul A. McNally, S.J., Ph.D.

George Washington University School of Medicine, 1335 H Street, N. W.—Organized in 1825 as the Medical Department of Columbian College. Also authorized to use the name "National Medical College." Classes were graduated in 1826 and in all subsequent years except in 1834-1838 and 1861-1863 inclusive. The original title was changed to Medical Department of Columbian University in 1873. In 1903 it absorbed the National University Medical Department. In 1904 by an Act of Congress the title of George Washington University was granted to the Institution. Coeducational since 1884. Sixty semester hours of college work were required for admission for the 1946-1947 and ninety hours will be required for the session beginning September 1947. The fees average $600 per academic year. An accelerated program was adopted June 8, 1942 and discontinued March 9, 1946. The registration for 1946-1947 was 310; graduates 79. The last session for freshmen, sophomores, and juniors began Sept. 30, 1946 and ended May 24, 1947; the last session for seniors began Sept. 30, 1946 and ended May 28, 1947. The next session for all classes will begin Sept. 15, 1947 and will end May 26, 1948. The Dean is Walter A. Bloedorn, M.D.

Howard University College of Medicine, Fifth and W Streets, N. W.—Chartered in 1867. Organized in 1869. The first class graduated in 1871. Coeducational since organization. Negro students compose a majority of those in attendance. The admission requirements are at least two years of collegiate work. The course covers four years of thirty-three weeks each. An accelerated program was adopted June 12, 1943 and was discontinued June 7, 1946. The fees are, respectively, $352.50; $347.50; $337.50 and $334.50. The registration for 1946-1947 was 267; graduates 62. The last session began September 28, 1946 and ended June 6, 1947. The next session will begin September 27, 1947 and will end June 4, 1948. The dean is Joseph L. Johnson, M.D.

GEORGIA

Atlanta

Emory University School of Medicine, 50 Armstrong St.—Organized in 1854 as the Atlanta Medical College. Classes graduated 1855 to 1861, when it suspended. Reorganized in 1865. A class graduated in 1865 and each subsequent year except 1874. In 1898 it merged with the Southern Medical College (organized in 1878), taking the name of Atlanta College of Physicians and Surgeons. In 1913 it merged with Atlanta School of Medicine (organized in 1905), reassuming the name of Atlanta Medical College. Became the School of Medicine of Emory University in 1915. Three years of collegiate work are required for admission. The course of study is four academic years; 32 weeks each in the 1st and 2nd years; 36 weeks in the 3rd year; 40 weeks in the 4th year. The fees for each of the four academic years are $600. An accelerated program was adopted June 15, 1942 and discontinued in March, 1947. The registration for 1946-1947 was 209; graduates, 55. The last session for freshmen and sophomores began Sept. 24, 1946 and ended June 15, 1947; the last session for juniors began Mar. 25, 1946 and ended Mar. 15, 1947; the last session for seniors began Mar. 25, 1946 and ended Feb. 28, 1947. The next session for freshman and sophomore classes will begin Sept. 18 and 22, 1947 and will end June 5, 1948; the next session for the junior class will begin Sept. 2, 1947 and will end June 5, 1948; the present session for the senior class began Aug. 1, 1947 and will end June 5, 1948. The Dean is R. Hugh Wood, M.D.

Augusta

University of Georgia School of Medicine, University Place.—Organized in 1828 as the Medical Academy of Georgia, the name being changed to the Medical College of Georgia in 1829. After 1873 it was known as the Medical Department of the University of Georgia. On July 1, 1933, the name was changed to the University of Georgia School of Medicine. Property transferred to the University in 1911. Classes were graduated in 1833 and all subsequent years except 1862 and 1863. Coeducation was begun in 1920. Three years of collegiate work are required for admission. An accelerated program was adopted July 1, 1942 and discontinued in April 1946. The fees average $225 per academic year for residents of Georgia, non-residents $525. Only bona fide residents of Georgia admitted (with exception of A. S. T. and V-12 Program students during World War II). The registration for the 1946-1947 session was 283; graduates 66. The 1946-1947 session for the junior and senior classes began April 11, 1946, and ended March 24, 1947; the freshman and sophomore classes began September 9, 1946, and ended June 19, 1947. The present session for the senior class began April 3, 1947, and will end March 22, 1948; the freshman, sophomore and junior classes will begin September 11, 1947, and will end June 19, 1948. The Dean is G. Lombard Kelly, M.D.

ILLINOIS

Chicago

Loyola University School of Medicine, 706 South Wolcott Avenue—Organized in 1915 by acquisition of Bennett Medical College which had been organized in 1869. Facilities enlarged by the acquisition of Chicago College of Medicine and Surgery, faculties in basic sciences put on full time basis and present title assumed in 1917. Operated as an organic part of Loyola University. Coeducational since organization. Ninety semester hours of collegiate work are required for admission. The fees for the academic year beginning September 22, 1947 will be $600.00. An accelerated program was adopted July 6, 1942 and discontinued October 1, 1945. The registration for 1946-1947 was 286, graduates 76. The last session for freshmen and sophomores began Sept. 30, 1946 and ended June 28, 1947; juniors began April 29, 1946 and ended March 29, 1947; the session for seniors began April 29, 1946 and ended February 8, 1947. The present session for seniors began April 8, 1947 and will end March 23, 1948. The next session for freshmen, sophomores and juniors will begin September 22, 1947 and will end June 26, 1948. The Dean is James J. Smith, M.D.

Northwestern University Medical School, 303 East Chicago Avenue.—Organized in 1859 as the Medical Department of Lind University. First class graduated in 1860. In 1864 it became independent as the Chicago Medical College. It united with Northwestern University in 1869 but retained the name of Chicago Medical College until 1891, when the present title was taken. Became an integral part of Northwestern University in 1905. Coeducational since 1926. The requirement for admission is 85 semester hours of collegiate work. The B.S. in medicine degree may be conferred before the end of the senior year. A hospital internship is required for graduation. An accelerated program was adopted June 17, 1942 and discontinued July 1, 1946. The total fees are $500 each year. The registration for 1946-1947 was 517; graduates, 156. The last session began for freshmen and sophomores September 27, 1946 and ended June 14, 1947. Juniors and seniors began March 27, 1946 and ended in March 1947. The next session will begin Sept. 26, 1947 and will end June 12, 1948. The Dean is J. Roscoe Miller, M.D.

University of Chicago, The School of Medicine, Fifty-Eighth Street and Ellis Avenue.—Organized in 1924, as a part of the Ogden Graduate School of Science of the University of Chicago. In 1932, when the University of Chicago reorganized its departments, the medical departments were included in the Division of Biological Sciences. The work the first two years in the medical courses has been given on the University Quadrangles since 1899; but the last two years were offered only at Rush Medical College which was affiliated with the university until 1927 when actual work in the clinical departments on the campus began. After that time, candidates for the degree of Doctor of Medicine could take the work of the first two years on the campus and the work of the third and fourth years either on the campus or at the Rush Medical College. In June 1940 Rush Medical College became affiliated with the University of Illinois College of Medicine. All undergraduate instruction is now given only on the campus of the University of Chicago. The requirements for admission are 90 semester hours of collegiate work. The B.S. degree may be obtained during the second year. The curriculum covers twelve quarters of work. Sixty-five students are admitted to the first year class each year. The tuition fee averages $600. The registration for 1946-1947 was 230; graduates, 62. Quarters begin in March, June, September and December of each year. All correspondence relating to general policies should be addressed to A. C. Bachmeyer, M.D., Associate Dean of the Biology Division, and that pertaining to student affairs to F. J. Mullin, Ph.D., Dean of Students.

University of Illinois College of Medicine, 1853 West Polk Street, Zone 12.—Organized in 1882 as the College of Physicians and Surgeons. The first class graduated in 1883. It became the Medical Department of the University of Illinois by affiliation in 1897. Relationship with the university was canceled in June 1912, and was restored in March 1913, when the present title was assumed. The staff of the Rush Medical College was incorporated in the University of Illinois College of Medicine in 1942 and at the same time Presbyterian Hospital, Chicago, became a teaching unit of the university. Coeducational since 1898. Three years of collegiate work are required for admission. The B.S. in medicine degree may be conferred at the end of the second year. An accelerated program was adopted June 15, 1942 and discontinued June 1946. The fees for residents of Illinois average $291 per academic year; non-residents pay an additional fee of $150. The registration for the 1946-1947 session was 635; graduates 161. The last session began Sept. 30, 1946 and ended June 20, 1947. The next session will begin Sept. 30, 1947 and will end June 19, 1948. The Dean is John B. Youmans, M.D.

INDIANA

Bloomington-Indianapolis

Indiana University School of Medicine, Bloomington, 1040 West Michigan Street, Indianapolis.—Organized in 1903 but did not give all the work of the first two years of the medical course until 1905. In 1907 by union with the State College of Physicians and Surgeons, the complete course in medicine was offered. In 1908 the Indiana Medical College, which was formed in 1905 by the merger of the Medical College of Indiana (organized in 1878), the Central College of Physicians and Surgeons (organized in 1879), and the Fort Wayne College of Medicine (organized in 1879) merged into it. The first class was graduated in 1908. Coeducational since organization. The B.S. degree in anatomy and physiology is conferred. Three years of college work are required for admission. The work of the first two semesters is given at Bloomington; the remainder of the work at Indianapolis. An accelerated program was adopted May 12, 1942 and discontinued April 23, 1946. Regular fee for two semesters of work is $221 for residents of Indiana and $426 for nonresidents. The registration for the 1946-1947 session was 396; graduates 98. The last session for sophomores, juniors and seniors began Sept. 23, 1946 and ended June 11, 1947. Freshmen began Oct. 18, 1946 and ended June 11, 1947. The next session will begin Sept. 22, 1947 and will end June 10, 1948. The Dean is John D. Van Nuys, M.D., Indianapolis.

IOWA

Iowa City

State University of Iowa College of Medicine, University Campus.—Organized in 1869. First session began in 1870. First class graduated in 1871. Absorbed Drake University College of Medicine in 1913. Coeducational since 1870. Three years of collegiate work are required for admission. The B.A. degree in the combined course of liberal arts and medicine is conferred. An accelerated program was adopted May 11, 1942 and discontinued June 15, 1946. The tuition fee is $230 each year for residents of Iowa and $490 for nonresidents. The registration for 1946-1947 was 291; graduates 74. The last session began for juniors and seniors April 1, 1946 and ended March 15, 1947 and for freshmen and sophomores the last session began September 23, 1946 and ended June 6, 1947. The present session for seniors began on March 24, 1947 and will end on March 13, 1948. The next session for freshmen, sophomores, and juniors will begin September 22, 1947 and will end on June 5, 1948. The Dean is Ewen Murchison MacEwen, M.D.

KANSAS

Lawrence-Kansas City

University of Kansas School of Medicine, Lawrence; 39th Street and Rainbow Boulevard, Kansas City.—Organized in 1880. It offered only the first two years of the medical course until 1905, when it merged with the Kansas City (Mo.) Medical College, founded in 1869, the College of Physicians and Surgeons, founded in 1894, and the Medico-Chirurgical College, founded in 1897. Absorbed Kansas Medical College of Topeka in 1913. The first class graduated in 1906. The clinical courses are given in Kansas City. At present the first year and one-half of the medical course is given on the University campus at Lawrence, Kansas. The class is transferred to the Kansas City, Kansas campus in the middle of the year where the balance of the course is given. Coeducational since 1880. The requirement for admission is three years of collegiate work. An accelerated program was adopted in June 1942 and discontinued June 21, 1946. The annual fees average $200 per year at Lawrence Division and $300 per year at Kansas City Division. The nonresident fees are $600 per year at the Kansas City Division. The registration for 1946-1947 was 287; graduates 73. The last session for junior and senior classes began March 18, 1946 and ended March 22, 1947 with a required "elective trimester" from March 24 to June 14, 1947. The freshman and sophomore classes began September 26, 1946 and ended June 14, 1947. The next session will begin September 17, 1947 and will end June 3, 1948. The Dean is Harry R. Wahl, M.D., Kansas City.

KENTUCKY

Louisville

University of Louisville School of Medicine, 101 West Chestnut Street, Zone 2.—Organized in 1837 as Louisville Medical Institute. The first class graduated in 1838, and a class graduated each subsequent year except 1863. In 1846 the name was changed to University of Louisville Medical Department. In 1907 it absorbed the Kentucky University Medical Department; in 1908, the Louisville Medical College, the Hospital College of Medicine and the Kentucky School of Medicine. In 1922 it changed its name to the University of Louisville School of Medicine. Coeducational since organization. Two years of collegiate work are the minimum requirements for admission. Preference is given applicants with a degree or three college years leading to a degree. An accelerated program was adopted July 1, 1942 and discontinued in the fall of 1947. Fees are $450 for residents of Louisville and Jefferson County and $550 for nonresidents, per school year. The registration for 1946 was 332; graduates 87. The last session began on April 1, 1946 and ended December 21, 1946. The present session began on Jan. 6, 1947 and will end on September 20, 1947. The subsequent session will begin on Sept. 29, 1947, and will end on June 15, 1948. The Dean is John Walker Moore, M.D.

LOUISIANA

New Orleans

Louisiana State University School of Medicine, 1542 Tulane Avenue, Zone 13.—Organized January 1931 as Louisiana State University Medical Center. Present title in 1939. Coeducational. First session October 1931, with students of first and third year. Course covers four sessions of not less than 32 weeks each. A minimum of three years collegiate work is required for admission. An accelerated program was adopted June 25, 1942 and discontinued May 25, 1946. Total fees, $123 each year for residents of Louisiana; additional tuition of $400 each year for nonresidents. The registration for 1946-1947 was 313; graduates 75. The last session began June 10, 1946 for junior and senior students and ended March 8, 1947. Freshman and sophomore classes began Sept. 9, 1946 and ended May 31, 1947. The present session began on April 9, 1947 for senior classes and will end May 22, 1948. Freshman, sophomore and junior classes will begin Sept. 4, 1947 and will end June 5, 1948. The Dean is Vernon W. Lippard, M.D.

Tulane University of Louisiana School of Medicine, 1430 Tulane Avenue.—Organized in 1834 as the Medical College of Louisiana. Classes were graduated in 1835 and in all subsequent years except 1863-1865, inclusive. It became the Medical Department of the Tulane University of Louisiana in 1884. Present title in 1913. Coeducational since 1915. A minimum of three years of collegiate work is required for admission. An accelerated program was adopted July. 1, 1943 and discontinued June 1, 1946. Total fees average $550 per academic year. The registration for the 1946-1947 session was 466; graduates 125. The last session began on Sept. 3, 1946 and ended June 11, 1947. The next session will begin Sept. 2, 1947 and will end June 2, 1948. The Dean is Maxwell E. Lapham, M.D.

MARYLAND

Baltimore

Johns Hopkins University School of Medicine, 710 North Washington Street.—The nucleus of a Medical Faculty was constituted in 1883. Systematic postgraduate instruction in pathology and bacteriology was begun in 1886. School was fully organized and opened in 1893. The first class graduated in 1897. Coeducational since organization. The requirement for admission is a college degree. The course extends over four years of eight and one-half months each. An accelerated program was adopted June 1, 1942 and discontinued March 19, 1946. The fees average $617 per academic year. The registration for 1946-1947 was 299; graduates 79. The last session began on Sept. 30, 1946 and ended June 10, 1947. The next session will begin on Sept. 29, 1947 and will end June 8, 1948. The Dean is Alan M. Chesney, M.D.

University of Maryland School of Medicine and College of Physicians and Surgeons, Lombard and Greene Streets, Zone 1.—Organized in 1807 as the College of Medicine of Maryland. The first class graduated in 1810. In 1812 it became the University of Maryland School of Medicine. Baltimore Medical College was merged with it in 1913. In 1915 the College of Physicians and Surgeons of Baltimore was merged and the present name assumed. Coeducational since 1918. Three years of college work is required for admission. An accelerated program was adopted June 25, 1942 and discontinued March 22, 1946. The tuition fees average $513.00 for residents of the state; for nonresidents $150 additional. The registration for 1946-1947 was 334; graduates 97. The last session began September 5, 1946 and ended June 7, 1947. The next session will begin September 18, 1947, and will end June 5, 1948. The Acting Dean is H. Boyd Wylie, M.D.

MASSACHUSETTS

Boston

Boston University School of Medicine, 80 East Concord Street.—Organized in 1873 as a homeopathic institution. In 1874 the New England Female Medical College, founded in 1848, was merged into it. The first class was graduated in 1874. Became nonsectarian in 1918. Coeducational since organization. Applicants are required to present a minimum of three years of premedical work. An accelerated program was adopted June 30, 1942 and discontinued in March 1946. Total fees average $575 per year. The registration for 1946-1947 was 244; graduates 57. The last session for freshmen, sophomores and juniors began Sept. 19, 1946 and ended June 7, 1947. The last senior class began June 3, 1946 and ended May 26, 1947. The present senior class began June 16, 1947 and will end June 7, 1948. All other classes will be enrolled Sept. 15, 1947 and the session will end June 5, 1948. The Dean is James M. Faulkner, M.D.

Harvard Medical School, 25 Shattuck Street, Zone 15.—Organized in 1782. The first class graduated in 1788. Two years of collegiate work are required for admission. An accelerated program was adopted July 1, 1942 and discontinued in June 1947. The fees average $610. The registration for 1946-1947 was 490; graduates 131. The present session began April 1, 1946 for juniors and seniors, and Sept. 23, 1946 for freshmen and sophomores and ended on June 5, 1947 for all four classes. The next academic year will begin Sept. 22, 1947 and will end June 10, 1948. The Dean is C. Sidney Burwell, M.D.

Tufts College Medical School, 416 Huntington Avenue.—Organized in 1893 as the Medical Department of Tufts College. The first class graduated in 1894. Coeducational since 1894. A bachelor's degree is required for admission. Enrolment is generally limited to residents of the New England states. The course covers four years. An accelerated program was adopted June 15, 1942 and discontinued in March 1946. The total fees for each of the four years, respectively, are $610, $605, $605, $615. The registration for 1946-1947 was 400; graduates 103. The last session began for freshmen, sophomores and juniors Sept. 25, 1946; for seniors April 8, 1946 and all classes ended June 15, 1947. The present session began for the seniors on June 9, 1947 and for the other classes will begin Sept. 24, 1947 and ends June 20, 1948. The Dean is Dwight O'Hara, M.D.

MICHIGAN

Ann Arbor

University of Michigan Medical School.—Organized in 1850 as the University of Michigan Department of Medicine and Surgery. The first class graduated in 1851. Present title assumed in 1915. Coeducational since 1870. The entrance requirements are ninety semester hours. An accelerated program was adopted June 15, 1942 and discontinued Sept. 23, 1946. The fees average $280 per academic year; for nonresidents $450 a year. The registration for 1946-1947 session was 500; graduates 140. The last session for seniors began Feb. 23, 1946 and ended Dec. 14, 1946; freshmen, sophomores and juniors began Sept. 23, 1946 and ended June 10, 1947. The next session will begin Sept. 22, 1947 and will end June 12, 1948. The Dean is Albert C. Furstenberg, M.D.

Detroit

Wayne University College of Medicine, 1516 St. Antoine Street.—Organized as the Detroit College of Medicine in 1885 by consolidation of the Detroit Medical College (organized in 1868) and the Michigan College of Medicine (organized in 1879). Reorganized with the title of Detroit College of Medicine and Surgery in 1913. The first class graduated in 1869. In 1918 it became a municipal institution under the control of the Detroit Board of Education. In 1934 the name was changed by action of the Detroit Board of Education to Wayne University College of Medicine, as a part of the program of consolidation of the Detroit city colleges into a university system. Coeducational since 1917. Entrance requirement is 90 semester hours from an accredited college or university. An accelerated program was adopted June 29, 1942 and discontinued June 14, 1947. Until further notice, enrolment is limited to residents of the state of Michigan. The fees average $525 for the school year. The registration for 1946-1947 was 230; graduates 62. The last session began July 8, 1946 and ended June 14, 1947. The next session will begin Sept. 15, 1947 and will end June 12, 1948. The Dean is Hardy A. Kemp, M.D.

MINNESOTA

Minneapolis

University of Minnesota Medical School, Zone 14.—Organized in 1883 as the University of Minnesota College of Medicine and Surgery and reorganized in 1888 by absorption of the St. Paul Medical College and Minnesota Hospital College. The first class graduated in 1889. In 1908 the Minneapolis College of Physicians and Surgeons, organized in 1883, was merged. In 1909 the Homeopathic College of Medicine and Surgery was merged. Present title in 1913. Coeducational since organization. An accelerated program was adopted June 17, 1942 and will be discontinued in the fall of 1947. The entrance requirements are three years of university work. Students are required to meet the requirements for a degree of B.S. or B.A. before receiving the degree of Bachelor of Medicine (M.B.), which is granted at the end of the course. The M.D. degree is conferred after a year of intern work, of advanced laboratory work, or of public health work has been completed. Total fees are $231 per academic year for residents and $450 for nonresidents. The registration for 1947 was 356; graduates 109. The present session began Jan. 6, 1947 and will end Sept. 12, 1947. The next session will begin Sept. 29, 1947 and will end June 12, 1948. The Dean is Harold S. Diehl, M.D.

MISSOURI

St. Louis

St. Louis University School of Medicine, 1402 South Grand Boulevard, Zone 4.—Organized in 1901 as the Marion-Sims-Beaumont Medical College by union of Marion-Sims Medical College, organized in 1890, and Beaumont Hospital Medical College, organized in 1886. First class graduated in 1902. It became the Medical School of St. Louis University in 1903. The completion of three years of college study is the minimum admission requirement but students presenting meritorious credits in excess of the minimum are accepted by preference. An accelerated program was adopted June 15, 1942 and discontinued March 16, 1946. The fees average $611 per academic year. The registration for 1946-1947 was 454; graduates 130. The last session began Sept. 17, 1946 and ended June 1, 1947. The next session will begin Sept. 16, 1947 and will end June 1, 1948. The Dean is Alphonse M. Schwitalla, S.J., Ph.D.

Washington University School of Medicine, Kingshighway and Euclid Avenue, Zone 10.—Organized in 1842 as the Medical Department of St. Louis University. The first class graduated in 1843. In 1855 it was chartered as an independent institution under the name of St. Louis Medical College. In 1891 it became the Medical Department of Washington University. In 1899 it absorbed the Missouri Medical College. Coeducational since 1918. Three years of college work is required for admission. The B.S. degree in medicine is conferred at the end of the third or fourth year. An accelerated program was adopted June 15, 1942 and discontinued March 23, 1946. The fees average $601. The registration for 1946-1947 was 367; graduates 97. The last session for juniors and seniors began on April 1, 1946 and ended June 12, 1947. The session for freshmen and sophomores began Sept. 16, 1946 and ended June 12, 1947. The next session will begin on Sept. 22, 1947 and will end in June 1948. The Dean is Robert A. Moore, M.D.

NEBRASKA

Omaha

Creighton University School of Medicine, 306 North Fourteenth Street, Zone 2.—Organized in 1892 as the John A. Creighton Medical College. The first class graduated in 1893. Present title in 1921. Coeducational since organization. Ninety semester hours of collegiate work are required for admission. An accelerated program was adopted July 7, 1942 and discontinued March 18, 1946. The tuition fees average $574 per academic year. The registration for 1946-1947 was 234; graduates 55. The last session began Sept. 27, 1946 and ended June 5, 1947. The next session will begin Sept. 26, 1947 and will end June 3, 1948. The Dean is Charles M. Wilhelmj, M.D.

University of Nebraska College of Medicine, Forty-Second Street and Dewey Avenue, Zone 5.—Organized in 1881 as the Omaha Medical College. The first class graduated in 1882. It became the Medical Department of Omaha University in 1891. In 1902 it affiliated with the University of Nebraska, with the present title. The instruction of the first two years was given at Lincoln and of the last two at Omaha until 1913, when the work of all four years was transferred to Omaha. Coeducational since 1882. Three years of college work are required for admission. The B.S. degree in medicine is conferred at the end of the second year. An accelerated program was adopted June 12, 1942 and discontinued in March 1946. The fees average $320 per academic year. The registration for 1946-1947 was 314; graduates 77. The last session for juniors and seniors began April 1, 1946 and ended March 22, 1947. The last session for freshmen and sophomores began Sept. 13, 1946 and ended June 7, 1947. The present session for seniors began March 26, 1947 and will end March 20, 1948. The next session for freshmen, sophomores and juniors will begin Sept. 19, 1947 and will end June 5, 1948. The Dean is Harold C. Lueth, M.D.

NEW YORK

Albany

Albany Medical College, 47 New Scotland Avenue.—Organized in 1838. The first class graduated in 1839. It became the Medical Department of Union University in 1873. In 1915 Union University assumed educational control. Coeducational since 1915. The requirement for admission is three years of college work. An accelerated program was adopted July 6, 1942 and discontinued in July 1946. The fees average $632 per academic year. The registration for 1946-1947 was 183; graduates 43. The last session began for freshmen Sept. 30, 1946 and ended June 21, 1947, sophomore and juniors March 25, 1946 and ended March 22, 1947 and April 5 respectively and seniors began April 1, 1946 and ended May 31, 1947. The present senior class began June 2, 1947 and will end May 31, 1948 and the juniors began April 7, 1947 and will end April 2, 1948. The next session will begin September 29, 1947 and will end June 10, 1948 for freshmen and sophomores. The Dean is R. S. Cunningham, M.D.

Brooklyn

Long Island College of Medicine, 350 Henry Street, Zone 2.—Chartered in 1930, was originally organized in 1858 as the Long Island College Hospital. From the collegiate department the first class graduated in 1860 and the last class in 1930. The first class of the Long Island College of Medicine was graduated in 1931. It is coeducational. Three years of collegiate work, including specified courses, are required for admission. An accelerated program was adopted July 6, 1942 and discontinued in March 1946. The fees are $665 per academic year. The registration for 1946-1947 was 398; graduates 95. The last session for juniors and seniors began April 1, 1946 and ended for juniors April 12, 1947, for seniors Feb. 15, 1947. The last session for freshmen and sophomores began on Sept. 23, 1946 and ended on June 14, 1947. The next session begins for freshmen, sophomores and juniors on Sept. 22, 1947 and ends June 12, 1948; for seniors Sept. 15, 1947 and will end June 10, 1948. The President and Dean is Jean A. Curran, M.D.

Buffalo

University of Buffalo School of Medicine, 24 High Street.—Organized in 1846. The first class graduated in 1847. It absorbed the Medical Department of Niagara University in 1898. Coeducational since organization. The minimum requirement for admission is three years of collegiate work including certain prescribed science subjects. An accelerated program was adopted July 6, 1942 and discontinued in June 1946. The fees for the entire course are $2,000. The registration for 1946-1947 was 276; graduates 69. The last session began on September 30, 1946 and ended June 21, 1947. The next session will begin September 22, 1947 and will end June 19, 1948. The Dean is Stockton Kimball, M.D.

New York

Columbia University College of Physicians and Surgeons, 630 West One Hundred and Sixty-Eighth Street.—The medical faculty of Columbia College, then known as King's College, was organized in 1767. Instruction was interrupted by the War of the Revolution. The faculty was reestablished in 1792 and merged in 1814 with the College of Physicians and Surgeons, which had received an independent charter in 1807. In 1860 the College of Physicians and Surgeons became the Medical Department of Columbia College. This merger became permanent by legislative enactment in 1891. Columbia College became Columbia University in 1896. The medical school has been coeducational since 1917. Three years of collegiate work are required for admission. An accelerated program was adopted July 7, 1942 and discontinued March 1946. Fees average $630 per academic year. The registration for 1946-1947 was 442; graduates 113. The last session began on March 28, 1946 for juniors and seniors and ended on June 3, 1947. The last session for freshmen and sophomores began on Sept. 12, 1946 and ended June 3, 1947. The present session began on June 9, 1947 and June 2, 1947 respectively, for the juniors and seniors and will end June 11, 1948, and will begin on Sept. 11, 1947 for the freshmen and sophomores and will end June 1, 1948. The Dean is Willard C. Rappleye, M.D.

Cornell University Medical College, 1300 York Avenue.—Organized in 1898. Coeducational since organization. First year teaching was given formerly to approximately one third of the class at Ithaca but in 1938 this division was discontinued and all instruction is now in New York City. All students admitted are from approved colleges for premedical training. The requirement for admission is three years of college work. The fees average $725 per year. An accelerated program was adopted July 8, 1942 and discontinued in June 1946. The registration for 1946-1947 was 322; graduates 83. The last session began for juniors and seniors April 4, 1946 and ended March 28, 1947. The freshman and sophomore classes began September 26, 1946 and ended June 19, 1947. The present senior class began March 31, 1947 and will end March 26, 1948. The next session for freshmen, sophomores and juniors will begin September 24, 1947 and will end June 17, 1948. The Dean is Joseph C. Hinsey, Ph.D.

New York Medical College, Flower and Fifth Avenue Hospitals, 1 East 105th Street.—Organized in 1858. Incorporated in 1860 as the Homeopathic Medical College of the State of New York. The title New York Homeopathic Medical College was assumed in 1869; the title New York Homeopathic Medical College and Hospital in 1887; the title New York Homeopathic Medical College and Flower Hospital in 1908; the title New York Medical College and Flower Hospital in 1936; the present title of New York Medical College, Flower and Fifth Avenue Hospitals, June 22, 1938. The first class graduated in 1861. Coeducational since 1919. Three years of college work are the minimum requirements; degree preferred. An accelerated program was adopted July 1, 1942 and discontinued September 1946. The fees average $664 per academic year. The registration for 1946-1947 was 458; graduates 112. The last session began September 9, 1946 and ended June 11, 1947. The next session will begin September 15, 1947, and will end June 9, 1948. The President and Dean is J. A. W. Hetrick, M.D.

New York University College of Medicine, 477 First Avenue, Zone 16.—The Medical Department of New York University (then called the University of the City of New York) was organized in 1841 as the University Medical College. In 1898 it united with the Bellevue Hospital Medical College, organized in 1861, under the name of University and Bellevue Hospital Medical College. In 1935 the name was changed to New York University College of Medicine. Coeducational since 1919. Entrance requirements give preference to those who have completed not less than three full years in an approved college of arts and sciences. An accelerated program was adopted June 1, 1942 and discontinued April 1, 1946. The fees average $650 per academic session. The registration for 1946-1947 was 486; graduates 120. The last session began September 23, 1946 for freshmen and sophomores and ended May 24, 1947. Juniors and seniors began April 8, 1946 and ended May 29 and June 11, 1947 respectively. The next session for all classes will begin September 22, 1947 and will end May 28, 1948. The Dean is Currier McEwen, M.D.

Rochester

University of Rochester School of Medicine and Dentistry, 260 Crittendon Boulevard, Zone 7.—Organized in 1925 as the Medical Department of the University of Rochester. Coeducational since organization. Three years of collegiate work are required for admission, except for veterans, who may be admitted with two years of collegiate work.

An accelerated program was adopted on July 6, 1942 and discontinued in June 1946. The fees are $600 per academic year. The registration for 1946-1947 was 269; graduates 66. The last session for juniors and seniors began March 25, 1946 and ended March 15, 1947. The session for freshmen and sophomores began September 16, 1946 and ended June 14, 1947. The present session began on March 17, 1947 for seniors and will end on March 27, 1948. The next session for freshmen, sophomores and juniors will begin on September 22, 1947 and will end on June 19, 1948. The Dean is George H. Whipple, M.D.

Syracuse

Syracuse University College of Medicine, 766 Irving Avenue, Zone 10.—Organized in 1872, when the Geneva Medical College, chartered in 1834, was removed to Syracuse, under the title "The College of Physicians and Surgeons of Syracuse University." Present title assumed in 1875, when a compulsory three year graded course was established. The first class graduated in 1873 and a class graduated each subsequent year. In 1889 the amalgamation with the university was made complete. Course extended to four years in 1896. Coeducational since organization. Three years of a recognized college course are required for admission. An accelerated program was adopted July 9, 1942 and discontinued July 1, 1946. The fees average $675 per academic year. The registration for 1946-1947 was 182; graduates 37. The last session began Sept. 2, 1946 and ended June 2, 1947. The next session for all classes will begin approximately Sept. 8, 1947 and will end June 14, 1948. The Dean is H. G. Weiskotten, M.D.

NORTH CAROLINA

Durham

Duke University School of Medicine.—Organized in 1930. The first class was admitted Oct. 1, 1930. Coeducational. The premedical requirement is three years of college work. The academic year consists of two semesters in the first year and three quarters each in the sophomore, junior and senior years. There is no summer quarter between the first and second year, but in the two clinical years the subjects of the autumn, winter and spring terms are repeated in the summer quarter. An accelerated program was adopted July 6, 1942 and starting with the summer quarter of 1946 this accelerated schedule will be optional, the students may take the two semesters of their first year, and three quarters in each of their subsequent years, and receive their certificates in four calendar years, or if they receive permission from the Curriculum Committee they may at the end of their second year take the clinical quarters given during the summers and receive their certificates in three and one quarter calendar years. The B.S. degree in medicine may be conferred for special work after six quarters. Students are urged to spend three years in hospital or laboratory work after graduation and must give assurance satisfactory to the executive committee that they will spend at least two years. Active duty with the Army, Navy or Public Health Service can replace the second year. The fees are $600 for each year of three quarters. The registration for 1946-1947 was 269; graduates 67. During 1947 the quarters begin January 6, March 31, July 7, October 6 and end March 22, June 14, September 20 and December 20. The next freshman class will be enrolled Oct. 6, 1947 and will end June 12, 1948. The Dean is Wilburt C. Davison, M.D.

Winston-Salem

Bowman Gray School of Medicine of Wake Forest College, Zone 7.—Organized in 1902 at Wake Forest as a school offering only the first two years of the curriculum. In 1941 the school was moved to Winston-Salem and expanded to a complete four year medical school under its present name. Coeducational. Ninety semester hours of college work are required for admission. An accelerated program was adopted June 29, 1942 and discontinued in June 1946. Clinical departments operate four quarters in the year, thereby making it possible for the student to complete the work for the degree of Doctor of Medicine six months short of the traditional four years. Students are encouraged during the junior and senior years to take one quarter out of each year, however, for research, for study elsewhere, or for earning money to help defray the expenses of their education. Tuition is $450 per school year. The registration for 1946-1947 was 172; graduates 38. The last session for the freshman class began September 25, 1946, sophomores September 30, 1946, juniors and seniors March 27, 1946 and ended for freshmen and sophomores June 7, 1947, for juniors March 15, 1947 and for seniors December 14, 1946. The present senior class began March 24, 1947 and will end December 13, 1947, juniors began July 7, 1947 and will end March 20, 1948. The next freshman and sophomore class will begin Sept. 29, 1947 and will end June 12, 1948. The Dean is C. C. Carpenter, M.D.

OHIO

Cincinnati

University of Cincinnati College of Medicine, Eden and Bethesda Avenues.—Organized in 1909 by the union of the Medical College of Ohio (founded in 1819) with the Miami Medical College (founded in 1852). The Medical College of Ohio became the Medical Department of the University of Cincinnati in 1896. Under a similar agreement, March 2, 1909, the Miami Medical College also merged with the University when the title of Ohio-Miami Medical College of the University of Cincinnati was taken. Present title assumed in 1915. Coeducational since organization. Liberal arts students of the University of Cincinnati may enroll for the seven year combined liberal arts and medical program. The B.S. degree is granted on the joint recommendation of the faculties of the College of Liberal Arts and Medicine at the end of the first medical year. An accelerated program was adopted June 29, 1942, and discontinued in April 1946. Tuition is as follows: for legal residents of Cincinnati $500 a year plus breakage fees ($50 additional for those not legal residents). The registration for 1946-1947 was 329; graduates 82. The last session for freshmen and sophomores began Sept. 20, 1946, and ended May 31, 1947. The session for juniors and seniors began March 4, 1946, and ended February 1, 1947. The next session for the freshmen, sophomore and junior classes will begin Sept. 22, 1947, and will end May 29, 1948. The present session for the senior class began February 4, 1947, and will end in February of 1948. The Dean is Stanley Dorst, M.D.

Cleveland

Western Reserve University School of Medicine, 2109 Adelbert Road, Zone 6.—Organized in 1843 as the Cleveland Medical College in cooperation with Western Reserve College. The first class graduated in 1844. The school assumed the present title in 1881. In 1910 the Cleveland College of Physicians and Surgeons was merged. Coeducational since 1919. The curriculum covers four scholastic years of 38 to 40 weeks each. Students are required to have three years of college work for admission. The fees average $600 per academic year. An accelerated program was adopted June 22, 1942 and discontinued March 15, 1946. The registration for 1946-1947 was 324; graduates 79. The last session began September 18, 1946 and ended June 7, 1947. The next session will begin September 17, 1947, for freshmen, sophomores and juniors and on September 1, 1947 for seniors, and the session for all classes will end June 5, 1948. The Dean is Joseph T. Wearn, M.D.

Columbus

Ohio State University College of Medicine, Neil and Eleventh Avenues, Zone 10.—Organized in 1907 as the Starling-Ohio Medical College by the union of Starling Medical College (organized in 1847 by charter granted by the State Legislature changing the name from Willoughby Medical College, which was chartered March 3, 1834) with the Ohio Medical University (organized 1890). In 1914 it became an integral part of the Ohio State University with its present title. Coeducational since organization. Three years of collegiate work are required for admission. An accelerated program was adopted June 23, 1942 and discontinued in June 1946. Tuition fees average $315 (increase to $465 autumn 1947) per academic year and $150 additional for nonresidents. The registration for 1946-1947 was 323; graduates 77. The last session began on Oct. 1, 1946 and ended June 9, 1947 for freshmen and sophomores; Mar. 26, 1946 and ended Mar. 15, 1947 for juniors and seniors. The present session began on March 25, 1947 for seniors and will end March 19, 1948; the present junior class began June 17, 1947 and will end March 19, 1948, freshmen and sophomores will begin September 30, 1947 and will end June 11, 1948. The Dean is Charles A. Doan, M.D.

OKLAHOMA

Oklahoma City

University of Oklahoma School of Medicine, 800 North East Thirteenth Street, Zone 4.—Organized in 1900. Until 1910 gave only the first two years of the medical course at Norman, Oklahoma, after which a clinical department was established at Oklahoma City through consolidation with the Medical School of Epworth University. The first class graduated in 1911. Coeducational since organization. A new medical school building and a second teaching hospital became available in 1928, and since September of that year the entire four year course has been given in Oklahoma City. Prerequisites for admission are three years—90 semester hours. An accelerated program was adopted May 10, 1943 and discontinued March 22, 1946. Fees: $50 "maintenance and incidental fee" per semester. Other annual course fees average $142, $129, $57 and $47, in the order given, beginning with the freshman year. For students not residents of Oklahoma there is a tuition charge of $350 a year, plus laboratory and course fees as indicated for the different years. The registrtaion for 1946-1947 was 275; graduates 70. The last session began September 16, 1946 and ended June 2, 1947. The next session will begin September 15, 1947 and will end June 1, 1948. The Dean is J. P. Gray, M.D.

OREGON

Portland

University of Oregon Medical School, Marquam Hill, Zone 1.—Organized in 1887. The first class graduated in 1888, and a class graduated each subsequent year except 1898. The Willamette University Medical Department was merged in 1913. Coeducational since organization. Entrance requirement is three years of collegiate work. An accelerated program was adopted June 22, 1942 and discontinued March 23, 1946. The total fees are, respectively, $388.50, $388.50, $383.50 and $390 for residents of Oregon and $60 a year additional for nonresidents. The registration for 1946-1947 was 277; graduates 69. The last session began October 2, 1946 and ended June 21, 1947. The subsequent session will begin September 30, 1947 and will end June 18, 1948. The Dean is D. W. E. Baird, M.D.

PENNSYLVANIA

Philadelphia

Hahnemann Medical College and Hospital of Philadelphia, 235 North Fifteenth Street, Zone 2.—Organized in 1848 as The Homeopathic Medical College of Pennsylvania. In 1869 it united with The Hahnemann Medical College of Philadelphia, taking the latter title. Assumed present title in 1885. The first class graduated in 1849. Coeducational beginning with 1941-1942 session. Three years of collegiate work in an approved college of arts and sciences are required for admission. An accelerated program was adopted July 27, 1942 and discontinued March 1946. Fees are respectively $655, $650, $650, $675. The registration for 1946-1947 was 459; graduates 132. The last session began for juniors and seniors April 8, 1946 and ended April 3, 1947 The last session began for sophomores September 30, 1946 and ended June 21, 1947. The last session began for freshmen September 22, 1946 and ended June 14, 1947 The present session began for seniors April 11, 1947 and will end March 18 1948 The next session will begin for juniors September 29, 1947 and will end May 29, 1948, for sophomores Sep 22, 1947 and will end June 12, 1948 The Dean is Charles L Brown, M D

Jefferson Medical College of Philadelphia, 1025 Walnut Street—Organized in 1825 as the Medical Department of Jefferson College, Canonsburg, Pa It was chartered with its present title in 1838 Classes have been graduated annually beginning in 1826 In 1838 a separate university charter was granted without change of title, since which time it has continued under the direction of its board of trustees For the class entering in 1948 the minimum entrance requirement will be three years of college work An accelerated program was adopted June 29, 1942 and discontinued Oct 1, 1946 The tuition fee is $600 a year The registration for 1946 1947 was 606, graduates 151 The last session began for juniors and seniors on April 15, 1946 and ended May 23, 1947, sophomores began October 1, 1946 and ended June 16, 1947, freshmen began October 1, 1946 and ended June 24, 1947 The next session for all classes will begin September 11, 1947 and will end June 4, 1948 The Dean is William Harvey Perkins M D

Temple University School of Medicine, 3400 North Broad Street, Zone 40—Organized in 1901 The first class graduated in 1904 Coeducational since organization Three years of collegiate work are required for admission An accelerated program was adopted July 1, 1942 and discontinued March 21, 1946 The fees average $610 per academic year The registration for 1946 1947 was 471, graduates 114 The last session began Sept 16, 1946 and ended June 19, 1947 The next session will begin Sept. 22, 1947 and will end June 17, 1948 The Dean is William N Parkinson, M D

University of Pennsylvania School of Medicine, Thirty Sixth and Pine Streets—Organized in 1765 Classes were graduated in 1768 and in all subsequent years except 1772 and 1775 1779, inclusive The original title was the Department of Medicine, College of Philadelphia The present title was adopted in 1909 It granted the first medical diploma issued in America In 1916 it took over the Medico Chirurgical College of Philadelphia to develop it as a graduate school Coeducational since 1914 Three years of collegiate work are required for admission The accelerated program was adopted July 27, 1942 and discontinued April 1946 The tuition fee is $600, with a deposit fee of $15, a general fee including student health of $15 and a matriculation fee of $5 The registration for 1946 1947 was 494, graduates 132 The last session for juniors and seniors began April 8, 1946 and ended March 15, 1947 The last session for freshmen and sophomores began Sept 23, 1946 and ended June 7, 1947 The present session began April 7, 1947 for seniors and will end Feb 28, 1948, and will begin on Sept 22, 1947 for freshmen sophomores and juniors and will end June 5, 1948 The Dean is Isaac Starr, M D

Woman's Medical College of Pennsylvania, Henry Avenue and Abbottsford Road Philadelphia 29—Organized in 1850 Classes were graduated in 1852 and in all subsequent years except 1862 At least three years of collegiate work are required for admission and candidates with a degree are given preference The curriculum covers four years of eight and one-half months each An accelerated program was adopted July 1, 1942 and discontinued June 15, 1946 Total fees are $675 yearly The registration for 1946 1947 was 151, graduates 35 The last session began September 11, 1946 and ended June 6, 1947 The next session will begin September 8, 1947 and will end June 5, 1948 The Dean is Marion Fay, Ph D

Pittsburgh

University of Pittsburgh School of Medicine, 3941 O'Hara Street—Organized in 1886, as the Western Pennsylvania Medical College and in 1908 became an integral part of the University of Pittsburgh, removing to the university campus in 1910 The first class graduated in 1887 Coeducation since 1899 Entrance requirements are two years of collegiate work An accelerated program was adopted July 6, 1942 and discontinued in April 1946 The total fees are $500 each year The registration for 1946 1947 was 319, graduates 83 The last session for juniors and seniors began April 8 1946 and ended March 22, 1947 The last freshman and sophomore classes began September 30, 1946 and ended June 28, 1947 The present session began on April 7, 1947 for seniors and will end March 27, 1948 and will begin on September 29, 1947 for freshmen, sophomores and juniors and will end June 26, 1948 The Dean is William S McEllroy, M D

Columbia

University of Missouri School of Medicine—Organized at St Louis in 1845, was discontinued in 1855 but was reorganized at Columbia in 1872 Teaching of the clinical years was suspended in 1909 Coeducational since 1872 The entrance requirements are 90 semester hours of collegiate work An accelerated program was adopted June 15, 1942 and discontinued Sept 21, 1946 The B S degree in medicine is conferred at the end of the second year Total fees for the first year are $266, for the second $255 The registration for 1946 1947 was 73 The last session began Sept 21, 1946 and ended June 5, 1947 The next session begins Sept 16, 1947 and will end June 4, 1948 The Dean is Dudley S Conley, M D

NEW HAMPSHIRE

Hanover

Dartmouth Medical School—Organized by Dr Nathan Smith in 1797 The first class graduated in 1798 It is under the control of the Trustees of Dartmouth College Courses of the third and fourth years were discontinued in 1914 Three years of college work and candidacy for the bachelor's degree are required for admission Candidates for the A B degree in Dartmouth College may substitute the work of the first year in medicine for that of the senior year An accelerated program was adopted May 25, 1942 and discontinued June 29, 1946 The tuition is $550 for each year The registration for 1946 1947 was 34 The last session began on September 30, 1946 and ended June 15, 1947 The next session will begin Oct 3, 1947 and will end June 13, 1948 The Dean is Rolf C Syvertsen, M D

NORTH CAROLINA

Chapel Hill

University of North Carolina School of Medicine—Organized in 1890 Until 1902 this school gave only the work of the first two years, when the course was extended to four years by the establishment of a department in Raleigh The first class was graduated in 1903 A class was graduated each subsequent year, including 1910, when the clinical department at Raleigh was discontinued Coeducational since 1914 Three years of college work are normally required for admission Certificates are awarded on the completion of two years' work in medicine An accelerated program was adopted June 15, 1942 and discontinued in June 1946 The fees for each year are $333 for the first year and $343 for the second year for residents, for nonresidents an additional fee of $100 per year The registration for 1946 1947 was 79 The North Carolina Legislature of 1947 appropriated funds for the expansion of the school to the full four years The full program will probably not get under way for three to four years The last session began Sept 16 1946 and ended in June 1947 The next session will begin September 22, 1947 and end in June 1948 The Dean is W Reece Berryhill, M D

NORTH DAKOTA

Grand Forks

University of North Dakota School of Medicine—Organized in 1905 Offers only the first two years of the medical course Coeducational since organization Three years work in a college of liberal arts are required for admission The B S degree in combined arts medical course is conferred at the end of the second year An accelerated program was adopted June 14, 1943 and discontinued in June 1946 The fees are about $120 each year for resident students and about $200 for nonresidents The registration academic year 1946 1947, was 49 The last session began Sept 23, 1946 and ended June 8, 1947 The next session will begin Sept 24, 1947 and will end June 13, 1948 The Dean is Alfred H Lawton, M D

SOUTH DAKOTA

Vermillion

University of South Dakota School of Medical Sciences—Organized in 1907 as the University of South Dakota School of Medicine Present title in 1937 Coeducational since organization Offers only the first two years of the medical course Three years work in a college of liberal arts are required for admission Students who complete the third year of premedical work in the College of Arts and Sciences at the University of South Dakota may apply the work of the first year of medicine to an A B degree The B S degree is conferred at the end of the second year on those students who do not hold a combination (Arts and Sciences and Medicine Course) A B degree An accelerated program was adopted June 15, 1942 and discontinued in September 1946 The tuition is $200 each year for residents and $450 for nonresidents The registration for 1946 1947 was 51 The last session began September 16, 1946 and ended May 25, 1947 The next session will begin September 8, 1947 and will end May 29, 1948 The Dean is Donald Slaughter, M D

WEST VIRGINIA

Morgantown

West Virginia University School of Medicine—Organized in 1902 Gives the first two years of the medical course, but agreement has been made for the transfer of 20 students each year to the Medical College of Virginia Coeducational since organization Entrance requirements are three years of collegiate work The B S degree in medicine is conferred at the end of the second year An accelerated program was adopted June 1, 1942 and discontinued in March 1946 Fees for residents of the state are, respectively, $254 and $264, nonresidents $150 additional each year The registration for 1946 1947 was 57 The last session began Sept 16, 1946 and ended June 2, 1947 The next session will begin Sept 15, 1947 and will end May 31, 1948 The Dean is Edward J Van Liere, M D

CANADA

Saskatchewan

University of Saskatchewan School of Medical Sciences Saskatoon—Organized in 1926 Coeducational Offers the first two years of the medical course Two years of collegiate work are required for admission The B A degree is conferred at the end of the second year The fees are $199 The registration for 1946 1947 was 50 The last session for freshmen began Sept 21, 1946 and ended June 21, 1947 and for sophomores Sept 9, 1946 to July 12, 1947 The next session will begin Sept 22, 1947 and will end June 22, 1948 The Dean is W S Lindsay, M B

ESSENTIALS OF APPROVED RESIDENCIES AND FELLOWSHIPS

(Revised to June 1947; originally published J. A. M. A. 90:922 [March 24] 1928)

Residencies and fellowships in the clinical branches of medicine, surgery and other specialties represent advanced training usually in preparation for the practice of a specialty. Residencies in specialties, as defined by the Council, are straight services of one or more years following an approved internship. A fellowship is a form of advanced training which in some cases is indistinguishable from a residency, although it usually offers greater opportunity for the study of basic sciences and research. Ordinarily a fellowship is a university rather than a hospital appointment. A general residency (also called a "mixed residency") is a general hospital assignment of one or more years after the internship. It usually does not carry credit toward certification by the American boards in the specialties but is *designed rather to provide additional general training.* All approved internship hospitals are also approved for general residencies.

Approved residencies and fellowships may be offered in the following branches of medicine; further information concerning these fields and thoir relationship to the established American boards are given in later sections of these "Essentials":

1. Allergy ‡
2. Anesthesiology *
3. Cardiovascular Disease §
4. Contagious Diseases
5. Dermatology and Syphilology *
6. Gastroenterology †
7. General Residency
8. Internal Medicine *
9. Malignant Diseases
10. Neurological Surgery *
11. Neurology *
12. Obstetrics and Gynecology *
13. Occupational Medicine
14. Ophthalmology *
15. Orthopedic Surgery *
16. Otolaryngology *
17. Pathology *
18. Pediatrics *
19. Physical Medicine
20. Plastic Surgery *
21. Proctology ♯
22. Psychiatry and Neurology *
23. Pulmonary Diseases †
24. Radiology *
25. Surgery *
26. Thoracic Surgery
27. Urology *

I. GENERAL REQUIREMENTS

Registration.—Previous approval as a registered hospital of the American Medical Association is essential for hospitals offering approved fellowships and residencies in specialties. (See the Council's "Essentials of a Registered Hospital.")

This implies that each hospital must be adequately organized, staffed and equipped, and that it be conducted primarily for the welfare of the sick. The educational functions described herein are supplementary to the main purpose of the hospital service but are closely related thereto in that they serve to improve the quality of medical practice.

Size.—The size of the institution is not a primary consideration. The clinical material, however, should be sufficient to enable residents to observe the principal manifestations of the disease conditions in the understanding and management of which they are acquiring further experience.

Plant and Equipment.—The physical plant should be such as to assure good medical and hospital care as well as the safety and comfort of the patients. There should be such equipment, appliances and apparatus as are commonly employed in the specialty in which the training is offered and in the use of which the resident should become proficient.

1. Staff

There should be an organized staff of ethical, licensed physicians holding the degree of doctor of medicine from medical schools acceptable to the Council on Medical Education and Hospitals of the American Medical Association. The particular specialties in which residents are being trained should be represented on the staff by well qualified, experienced and proficient physicians, whether or not they may be certified in a specialty or hold memberships in special societies.

In general hospitals, the staff should be organized into departments in those branches of medicine in which residencies are offered, with a competent director of each service, whose qualifications are acceptable to the Council. The director should assume responsibility for the training of residents and should require others of his staff to give the instruction and sympathetic cooperation which residents require.

It is essential that there shall be at least monthly clinical-pathologic conferences or other regular staff meetings at which the histories, clinical observations, laboratory studies and pathology of selected cases are reviewed. In addition to meetings of the staff as a whole, it is expected that departmental conferences shall be conducted in which residents should take an active part, so that the quality of the service given by that department to its patients may be recurringly evaluated. Other educational activities requiring full support of the staff are described under Training Program, Applied Basic Sciences, and Teaching and Investigation, sections I-8, I-9, and I-10, and Special Requirements, section II.

2. Department of Radiology

The department of radiology should be under the direction of a qualified radiologist proficient in the various functions of his specialty. He must likewise cooperate fully in the training of all hospital residents and supervise any direct contact which they may have with the work of the department. The department should contain appropriate and modern roentgenographic, roentgenoscopic and, where required, therapeutic equipment and radium. It should keep adequate cross-indexed records. These facilities are essential in institutions offering approved residency or fellowship programs in any field.

A description of the special requirements for a residency in radiology is given in section II-24.

3. Department of Pathology

The department of pathology should be under the direction of a qualified pathologist who shall be prepared to cooperate fully in the training of all hospital residents and supervise any direct contact which they have with the laboratory. This department should assume much of the responsibility for the clinical pathologic conferences. The department should provide apparatus, reagents and materials necessary for the operation of a modern clinical and pathologic laboratory, and maintain satisfactory records, with cross-indexing. Adequate necropsy facilities and instruction are also necessary.

A description of the special requirements for an approved residency in pathology is given in section II-17.

4. Necropsies

Thoroughness in postmortem performance should be emphasized. All institutions and individual clinical services desiring approval for the training of residents must maintain a satisfactory percentage of postmortem examinations. Complete necropsy records should be kept on file and each should contain a summary of the clinical record and detailed description of both the gross and the microscopic observations. Residents of all departments should attend postmortem examinations as often as possible. They may, with value, participate in the performance of necropsies; in the analysis of microscopic findings on materials derived from their own service and in the preparation of the protocols.

---

* Specialists may be certified in this specialty by an American board fulfilling the Council's "Essentials for Approved Examining Boards in Specialties."

† Specialists may be certified in this specialty by the American Board of Internal Medicine; applicants must first fulfill certification requirements in Internal Medicine.

§ Specialists may be certified in this specialty by the American Board of Internal Medicine; applicants must first fulfill certification requirements in Internal Medicine or Pediatrics.

♯ Specialists may be certified in this specialty by the American Board of Surgery; applicants must first fulfill certification requirements in Surgery.

‡ Specialists may be certified in this specialty by the American Board of Internal Medicine or the American Board of Pediatrics; applicants must first fulfill certification requirements in Internal Medicine or Pediatrics.

5. Medical Library

Institutions offering approved residencies and fellowships should maintain or provide ready access to an adequate medical library containing modern texts and monographs, the Quarterly Cumulative Index Medicus and current scientific and professional journals relating to the fields in which residencies and fellowships are offered. Lists of texts and journals which may be included in the libraries for the various specialties are available from the Council.

6. Histories and Records

There must be complete records, including the patient's complaint, case history, physical examination at the time of admission, a provisional diagnosis, laboratory observations, therapy employed, descriptions of operations if any, suitable progress notes, consultations, final diagnosis, condition on discharge, necropsy observations in case of death if postmortem examination is performed, and an appropriate summary.

The records should show by signatures, or initials, the names of all persons writing them or parts of them as well as the names of the staff members by whom the records are verified. Likewise, all orders and progress notes should be initialed or signed. Each completed history should be verified by a staff member.

The record department should be under the supervision of some competent person, preferably a trained medical record librarian. Alphabetical and diagnostic indexes of the patients should be maintained and the records filed so as to be readily accessible. Operative procedures and radiologic and pathologic material should likewise be classified in a suitable manner. The employment of the Standard Nomenclature of Disease and Operations is strongly recommended.

7. Eligibility of Applicants

Candidates for residencies or fellowships should be selected from graduates of medical schools acceptable to the Council on Medical Education and Hospitals of the American Medical Association who have served an internship in an approved hospital or have had two or more years in practice. It is recommended, however, that candidates seeking residencies or fellowships in such special fields of surgery as urology, orthopedics, plastic surgery, thoracic surgery, neurological surgery or proctology should first have completed one year of general surgical training beyond the internship.

8. Training Program

The educational effectiveness of a residency or fellowship program depends largely on the quality of its supervision and organization. It is important, therefore, that methods of instruction be employed which are best suited to the special field. Emphasis should be placed on bedside instruction, clinical experience, related laboratory studies, teaching rounds, departmental meetings or seminars, clinical-pathologic conferences, demonstrations and lectures. Familiarity with, and critical analysis of pertinent medical literature, is an important feature of residency training.

Aside from the daily contact with patients and the attending staff and participation in the organized educational program, the assumption of responsibility is a most valuable aspect of residency and fellowship training. Consequently, as ability is demonstrated, an increasing amount of reliance should be placed in the judgment of residents in diagnosis and in treatment as well as in the teaching of interns and/or medical students.

From the point of view of medical education, many residencies and fellowships are designed primarily to provide the training required for practice in some specialty of medicine. A given approved residency may not provide complete training in a specialty field, but each service that is properly organized will make a substantial contribution to the program of advanced training. Ordinarily, the duration of an approved residency or fellowship should be at least twelve months and might well be extended to two or more years when suitable facilities are available.

Most residency programs are designed to meet the needs of physicians seeking certification by an American board. Therefore in fields represented by the American boards, the Council seeks to approve only such residencies or fellowships as will be acceptable in whole or in part for admission to the certification examinations.

Although some residency hospitals will benefit by affiliation with medical schools, it is possible to conduct acceptable programs without such affiliation. Many approved hospitals must necessarily organize their residencies independently of medical schools including provision for training in the applied basic medical sciences.

9. Applied Basic Medical Sciences

Competence in any of the various specialties in clinical medicine requires a knowledge of the basic medical sciences employed in that specialty. Therefore, residency and fellowship programs acceptable to the Council and the American boards must provide for training in the applied basic medical sciences. Such training does not necessitate formal course work, specific assigned laboratory exercises, or affiliation of the residency hospital with a medical school; it should be distinctly of an applied nature, closely integrated with the clinical experience of the resident.

Any resident seeking competence or certification in a specialty must be able to apply at least the following basic sciences to his special field of medicine: anatomy, bacteriology, biochemistry, pathology, pharmacology and physiology. Undergraduate education in an approved medical school provides a background for an understanding of these sciences, so that the special training of the residency should not include hasty and inadequate reviews of these subjects, but rather their application to a given specialty.

Anatomy.—Anatomy at the residency level may well be taught, reviewed or learned from the living body, on the operating or examining table or from the fresh tissues in the pathological laboratory. More important in anatomical instruction of residents than an available anatomical laboratory is the attitude and enthusiasm of the hospital staff in availing themselves of opportunities to teach and learn applied gross and microscopic anatomy from clinical and pathological material. Opportunities for anatomical dissection, when available, may be utilized for supplementary training.

Bacteriology.—The hospital facilities and professional personnel in bacteriology, and in the allied sciences of parasitology, mycology, immunology and serology, should be such as to afford the resident opportunity and incentive to broaden his existing knowledge in these subjects in the light of his special clinical assignments and interests.

Biochemistry.—The hospital biochemistry laboratory should provide the resident with opportunities to broaden his knowledge of biochemistry as related to such clinical problems as he may encounter in his specialty; for example, water balance, acid-base equilibrium, glucose tolerance, and blood or urine levels of significant metabolic, nutritional or therapeutic elements. Such applied basic science work in biochemistry may be far more valuable than a formal review course in the field.

Pathology.—In a well conducted department of pathology of an acceptable residency hospital there is opportunity for correlating much basic medical science material with problems of clinical medicine. Applied gross and microscopic anatomy may be effectively learned from necropsy and surgical specimens. The clinical-pathologic conference should and can be one of the most effective devises for correlation of the basic sciences with clinical medicine.

Pharmacology.—Since the principles of pharmacology are involved in every therapeutic administration of chemical substances to patients, the wards of the residency hospitals provide very suitable opportunities for the resident to apply and expand the knowledge of pharmacology previously gained in medical school.

Physiology.—Historically, one of the most fruitful fields of investigation into the normal functions of the body has been the study of abnormality of function to which the resident in clinical medicine is constantly exposed. Clinical medicine affords a rich field for the study of physiology and a potent stimulus to the resident to apply the basic principles of this science. Much of the equipment and special apparatus employed in clinical studies of the patient are likewise used in physiology, so that clinical studies provide ample opportunity and stimulation for the resident to supplement his knowledge of physiology with applications of the science to clinical problems. Encouragement and opportunity for an enlarged understanding of body function in health and disease should be part of the experience of the resident in any of the specialties in the course of his clinical work.

10. Teaching and Investigation

Residents and fellows should be assigned to teaching responsibilities as their experience increases. The stimulating teacher-student relationship should be part of the resident's experience, not only as the student of the attending physician, but as the teacher of interns and nurses and, in medical school hospitals, of junior and senior medical students.

When the facilities of an institution warrant, and when the residents are competent and interested, they should be encouraged to engage in research, not only as an educational experience, but to increase the effectiveness of the hospital and its staff in caring for the sick. Such investigation may take the form of research in the hospital laboratories or wards, summaries of medical literature, or the preparation of statistical analyses derived from the hospital record department.

Affiliation of a residency hospital with a medical school is not essential for an acceptable educational program. Those hospitals having such an affiliation are in a position to provide the interested resident with educational opportunities supplementary to the training required for competence in the specialty. Such opportunities lie particularly in the fields of advanced laboratory training and research. Qualified and interested residents and fellows should be encouraged to undertake research programs at medical schools, within the limitations of available facilities. Interruption of the hospital assignments with a period of research under medical school guidance may be of inestimable value. While medical school affiliations have greatly strengthened residency and fellowship programs, many approved hospitals are able to conduct acceptable programs without such affiliations.

II. SPECIAL REQUIREMENTS

The following regulations pertaining to individual specialties describe the special training, in addition to the foregoing, required for competence in the practice of the various specialties of medicine and for admission to the examinations of the American boards in those specialties. Residents who plan to seek certification by an American board should communicate with the secretary of the appropriate board, as listed in Section IV, to be certain regarding the full requirements for certification.

1. Allergy (See Internal Medicine, Pediatrics.)

2. Anesthesiology

The director of the department should be a qualified physician limiting his practice to anesthesiology and competent to supervise the technical and educational activities of the department. His staff should include an adequate number of trained anesthetists in accordance with the needs of the service.

Equipment must be satisfactory for the teaching of modern methods of anesthesiology and should include suitable apparatus for gas administration, spinal anesthesia, resuscitation and inhalation therapy. Likewise, the clinical material must be sufficient to afford residents adequate experience in the various methods and types of anesthesia now commonly employed. Residencies in anesthesiology should provide systematic clinical and technical instruction supplemented by appropriate seminars, lectures and demonstrations on anatomic and other material.

See also the General Requirements for all residencies as given in Section I of these "Essentials."

Quantitative Requirements.—It is expected that each resident should administer approximately 500 anesthetics a year.

Applied Basic Science Instruction.—Applied anatomy, biochemistry, pharmacology and physiology are especially desirable and should be closely correlated with clinical experience. See Section I-9 of these "Essentials" for a discussion of applied basic medical science instruction.

Board Requirements.—The American Board of Anesthesiology requires candidates for the certification examination to have five years after the internship of active experience limited to anesthesiology, of which at least two years is devoted to acceptable supervised clinical training in this specialty.

3. Cardiovascular Disease (See Internal Medicine.)

4. Contagious Diseases

Training programs in contagious diseases might well follow the general pattern of work described for internal medicine or pediatrics, or both.

Although there is no certification in contagious diseases as such, training credit for six months in approved residencies in this field may be granted by the American Boards of Internal Medicine and of Pediatrics. A well balanced service is essential for residency training in contagious diseases. Between 300 and 400 admissions a year may be considered sufficient, especially if most of the acute contagious diseases are well represented.

5. Dermatology and Syphilology

The practice of dermatology and syphilology is concerned largely with ambulatory patients, so that it is essential that an active outpatient service be available to furnish sufficient clinical material in the various divisions of the specialty. It is also desirable that hospital facilities be available and that residents be given an opportunity to observe the dermatologic manifestations of the acute contagious diseases. There should be a well organized course of instruction involving lectures, seminars, clinical demonstrations and laboratory assignments, especially in histopathology, parasitology, mycology, and immunology. To facilitate clinical and laboratory teaching it is essential that the department have ready access to an adequate supply of classified anatomic and pathologic material including histologic and lantern slides for demonstrations. Projection apparatus should be available and also facilities for clinical photography.

See also the General Requirements for all residencies as given in Section I of these "Essentials."

Quantitative Requirements.—Ordinarily a minimum of 1,500 new outpatients a year is considered essential in the dermatologic division and a similar number in syphilology.

Applied Basic Science Instruction.—The residency should include organized study in the various applied basic sciences as related to clinical dermatology, especially in bacteriology, immunology, mycology, parasitology, serology, biochemistry, embryology, histology, pathology, pharmacology and physiology, as well as physics as related to therapy by physical agents. See Section I-9 of these "Essentials" for a discussion of applied basic medical science instruction.

Board Requirements.—The American Board of Dermatology and Syphilology requires candidates for the certification examination to complete three years of systematic instruction after the internship and two additional years of study or practice. The period of specialized training following internship shall include not less than eighteen months of active experience in clinical dermatology and syphilology and organized study in the applied basic medical sciences.

6. Gastroenterology (See Internal Medicine.)

7. General Residency

General residencies (also called "mixed residencies") are hospital assignments of a general type after the internship. While providing additional general training, they ordinarily carry no credit toward certification by the specialty boards. All hospitals approved for intern training are automatically accredited for general residencies. Other general hospitals may be approved for such work provided (*a*) they conform to the general requirements for residency training, as described in Section I of these essentials and (*b*) there is an admission rate of at least 1,500 patients per year.

8. Internal Medicine

Residencies and fellowships in internal medicine should be organized on a broad basis to furnish instruction in the various specialties which combine to form the foundation of practice in internal medicine. Accordingly, the service should not be limited entirely to general medicine and its subdivisions of allergy, cardiovascular disease, gastroenterology, metabolic diseases, contagious diseases and pulmonary diseases but might well include a reasonable amount of instruction in the divisions of psychiatry and neurology, dermatology and syphilology, and pediatrics, now organized as independent specialties.

In institutions offering residencies and fellowships in internal medicine, and in the special fields of allergy, cardiovascular disease, gastroenterology or pulmonary diseases, emphasis should be placed on the educational features of the service and residents should receive regular instruction from members of the staff in methods of clinical study and diagnostic and therapeutic procedures. Of particular importance is the study of etiology, pathogenesis, symptomatology and course of the various diseases so that the residents may develop skill and accuracy in diagnosis as well as a mature judgment and resourcefulness in therapy.

Under the supervision of qualified members of the staff the residents should assume individual responsibility in actual case management. They should also be required to correlate clinical studies with postmortem pathology, review medical literature and take an active part in weekly teaching rounds, departmental seminars and clinical-pathologic conferences.

See also the General Requirements for all residencies as given in Section I of these "Essentials."

Quantitative Requirements.—For approval a residency in internal medicine should have at least 400 annual admissions.

Applied Basic Science Instruction.—Anatomy, bacteriology, biochemistry, pathology, pharmacology and physiology are especially desirable and should be closely correlated with clinical experience. See Section I-9 of these "Essentials" for a discussion of applied basic medical science instruction.

Board Requirements.—The American Board of Internal Medicine requires candidates for the certification examination to have an approved internship of at least twelve months, three years of special training and two additional years of practice in the field of internal medicine or its more restricted and specialized branches. Not more than one year of instruction in the related medical specialties and basic sciences can be applied to the three year period of special training. General (or "mixed") residencies are ordinarily not regarded as satisfying any part of the required training. Also, a second year of internship will be recognized only if the second year is limited entirely to the medical service in a hospital which is approved by the Council on Medical Education and Hospitals for resident training in internal medicine. Physicians seeking certification in one of the special branches of internal medicine (i.e., allergy, cardiovascular disease, gastroenterology and pulmonary diseases) must first fulfill all the requirements for certification in internal medicine, including the examination.

Special Fields of Internal Medicine.—Residencies may be offered in the special fields of allergy, cardiovascular disease, gastroenterology or pulmonary diseases. Residencies in these fields should follow the general pattern described above for internal medicine as well as the following:

Allergy (See also allergy under pediatrics).—The objective of intensive training in allergy is to fit the physician for the highest type of practice, teaching and research in this specialty. A residency in allergy should comprise at least one though preferably two years of full time work. Residents in allergy should be given a thorough training in the fundamentals of human and animal sensitization through clinical study and laboratory experiments. There should be daily conferences or consultations with the staff. Reading of current articles and reviews of special topics should be assigned. Residents should be given responsibility for diagnosis and management of various diseases of allergy, for the teaching of interns, medical students and nurses as capability has been demonstrated. Problems in clinical or laboratory allergy should be utilized to develop an interest in research.

If the allergy service is not under the Department of Medicine, it should have inter-departmental associations so arranged as to give residents of the allergy unit continuing contact with the general medical (or pediatric) services through ward rounds, clinical-pathologic conferences, staff meetings, and so forth. The service should admit 200-300 ambulatory patients yearly, and have facilities for hospitalizing bed patients, in addition to cases seen in consultation with other services. It should have adequate laboratory facilities for those special chemical-immunologic, pathologic and bacteriologic procedures required in its field. The training of residents in allergy should be arranged to fit into the established programs of the American Boards of Internal Medicine or Pediatrics. Candidates for positions offering specialized training in allergy should previously have fulfilled the basic requirements of the parent board before undertaking study in the special field.

Certification in allergy is granted only to those who have previously fulfilled all the requirements for certification in internal medicine or pediatrics, including the examination.

Cardiovascular Disease.—In general, residencies in this field should follow the general pattern of residencies in internal medicine. There should be opportunities and facilities for the study of all types of cardiovascular disease, both acute and chronic. It is important that there be adequate opportunity for the study of such cardiac disorders in childhood as rheumatic heart disease and congenital abnormalities. There should be provisions for experience with peripheral vascular disease and electrocardiography. Clinical or experimental investigation should be encouraged. The number of patients admitted to this service may not be an accurate index of the available clinical material, since a large part of the material is commonly supplied on a consultation basis.

Certification in cardiovascular disease is granted only to those who have previously fulfilled all the requirements for certification in internal medicine or pediatrics, including the examination.

Gastroenterology.—Training in gastroenterology should take place not only in the hospital but also in the outpatient clinic. A hospital service of at least 10 beds or 200 admissions a year and work in a well organized gastroenterologic clinic for ambulatory patients admitting at least 200 patients a year should be considered sufficient, provided the service and its staff are acceptable. The resident, in addition to working in the department, should have careful instruction in actual care of patients and the following diagnostic and therapeutic measures: (*a*) fluoroscopy and the interpretation of roentgenograms of the gastrointestinal tract and its accessory organs; (*b*) endoscopy, including proctoscopy, gastroscopy and peritoneoscopy; (*c*) laboratory procedures, including analysis of gastric contents, bile and feces, tests of hepatic and pancreatic function, and the evaluation of these and ancillary laboratory findings with respect to their bearing on disease and disorders of the gastrointestinal and biliary tract; (*d*) the surgical aspects of gastrointestinal diseases, including consultation with surgeons, recognition of indications for operation, familiarity with operative procedures, and presence at operations on gastroenterologic patients wherever possible and (*e*) medical care of gastrointestinal diseases, including careful study of diet and nutrition, and the effects of drugs and other therapeutic measures on the gastrointestinal tract.

Original research work in gastroenterology could well be included in the previous residency in internal medicine and continued in the gastroenterologic residency fellowship only so far as it would not interfere with the essential training program outlined above.

Certification in gastroenterology is granted only to those who have previously fulfilled all the requirements for certification in internal medicine, including the examination.

Pulmonary Diseases.—Training in pulmonary diseases should be of such a character that residents may become thoroughly familiar with the various phases of institutional service in pulmonary diseases as well as the community aspects of tuberculosis control. This necessitates a well organized program of instruction with rotating assignments in the admitting department, infirmaries, convalescent and ambulatory wards and the outpatient clinics. Careful instruction should be provided in diagnosis, interpretation of roentgenograms, therapeutic procedures and general sanatorium care. It is particularly important that the residents become fully acquainted with the use of air or gas injection and the technic of the initial induction as well as the subsequent refills. If a surgical department is maintained, the operative service may be combined with the general training in pulmonary diseases or it may form the basis of a separate residency in thoracic surgery.

It must be emphasized that residencies in pulmonary diseases are educational in character and that of the full time sanatorium staff only those physicians who serve primarily on an educational basis come within the residency classification of the Council.

The clinical material must be adequate in kind and amount. Approximately 125 inpatients a year may be sufficient for a residency in pulmonary diseases.

Certification in pulmonary diseases is granted only to those who have previously fulfilled all the requirements for certification in internal medicine, including the examination.

9. Malignant Diseases

The division of malignant diseases is largely a combination of services involving practically all the branches of medicine and surgery, including pathology and radiology. It is important, therefore, that competent staff physicians be assigned to all departments and that special facilities be available for pathology, operative surgery, diagnostic roentgenology, therapeutic roentgenology and radium therapy.

The clinical material should be sufficient in kind and amount to enable residents to observe and study the various types of malignant diseases and the methods of therapy commonly employed. A teaching service should have approximately 350 inpatients a year and additional material in the outpatient tumor clinic.

Ordinarily, the training is general in type with assignments in clinical diagnosis, pathology, surgery, diagnostic roentgenology, therapeutic roentgenology and radium therapy. Courses in surgical and postmortem pathology, radiophysics and radiobiology are often included. In some instances the service is limited in scope and is utilized primarily as supplementary training in surgery, pathology, or radiology.

Although there is no certification in malignant diseases as such, some credit toward eligibility for the certification examinations may be granted by the American Boards of Surgery, Pathology and Radiology.

10. Neurological Surgery

Institutions offering residencies in neurological surgery should provide adequate facilities for the practice and teaching in this field. The clinical material must be sufficient to provide experience in the various phases of the subject. It should include an adequate number of cases of traumatic injury of the central nervous system, cerebral and spinal neoplasms, and surgical disorders of the peripheral and sympathetic nervous systems. Close contact between the residents and the neurological surgeons and others responsible for the diagnosis and care of the patients is essential. It is likewise essential that the resident staff participate actively in the diagnosis, operative treatment and post-operative care of the patients and not serve merely as onlookers. The residency should constitute a full time service. The period of training should be chiefly clinical rather than didactic. It should be concerned primarily with the diagnosis and treatment of neurosurgical disorders. With this training program there should be a concurrent program of training in the applied basic sciences, in diagnostic neurology, and in neurological roentgenology and ophthalmology. To qualify for approval for the three full years of training in this field a residency must provide experience in all the phases of neurological surgery. However, some residencies may qualify to supply a part of the requisite training in one or more of the essential phases.

The surgical training should be sufficient to insure a reasonable degree of technical experience and skill. The resident should have the opportunity to undertake some operative work under competent supervision, especially toward the end of his training program.

See also the General Requirements for all residencies as given in Section I of these "Essentials."

Quantitative Requirements.—An acceptable residency in this field requires an annual admission rate of at least 150 patients.

Applied Basic Science Instruction.—Organized basic science work as applied to neurological surgery is especially desirable in anatomy, pathology and physiology. This should be closely correlated with clinical experience. See Section I-9 of these "Essentials" for a discussion of applied basic medical science instruction.

Board Requirements.—The American Board of Neurological Surgery requires candidates for the certifying examination to have at least one year of general surgical training or a one year's assistant residency in general surgery before beginning their training in neurological surgery. The special training in neurological surgery consists of at least three years training in an approved residency. A period of two years of practice or further study in the specialty is also required.

11. Neurology (See Psychiatry and Neurology.)

12. Obstetrics and Gynecology

Institutions offering residencies or fellowships in obstetrics and/or gynecology must provide gynecological and/or obstetric facilities adequate for the clinical and teaching needs of the service. They should also furnish sufficient teaching material to afford residents a wide experience in clinical diagnosis, treatment, and technical and operative procedures.

Emphasis should be placed on clinical training in order that residents may receive ample instruction in the various phases of obstetric and gynecologic service, such as antepartum care, treatment of toxemias of pregnancy, management of normal and abnormal labor, technic of versions, breech extractions and instrumental delivery, diagnosis and treatment of the complications of labor, postpartum hemorrhage, puerperal infections, varieties of cesarean section and their indications, medical gynecology and its relation to endocrinology, minor procedures for ambulatory patients, and standard operations. Courses of instruction should include assignments in pathology, demonstrations on the manikin, departmental seminars, clinical-pathologic conferences and teaching rounds. Training in surgical technic should be sufficient to enable residents to undertake operative work on their own responsibility especially toward the end of the residency program. Prenatal and follow-up clinics are essential to the program.

See also the General Requirements for all residencies as given in Section I of these "Essentials."

Quantitative Requirements.—Ordinarily an admission rate of 400 patients a year is desirable in each of the fields of obstetrics and gynecology whether these are separate or combined services.

Applied Basic Science Instruction.—Applied anatomy, bacteriology, biochemistry, embryology, pathology and physiology are especially desirable and should be closely correlated with clinical experience. See Section I-9 of these "Essentials" for a discussion of applied basic medical science instruction.

Board Requirements.—The American Board of Obstetrics and Gynecology requires candidates for the certification examination to have completed a year of internship and seven years of practice including at least three years of acceptable training in obstetrics and gynecology. Although an applicant may be practicing primarily in one of the branches (obstetrics or gynecology), a knowledge of the fundamentals of the other branch is required.

13. Occupational Medicine

Residencies and fellowships in this field should be organized in the light of the principal components of occupational medicine: health conservation, occupational medicine and surgery, environmental hygiene and administration. To provide such training there should preferably be a combination of hospital and industrial in-plant assignments.

The hospital shall meet the general requirements for residency approval. There should be organized services in the hospital under competent staff direction in internal medicine, dermatology, ophthalmology, traumatic surgery, neurology and psychiatry. A well equipped rehabilitation center should be supplied. A hospital affiliated with a medical school or school of public health is in an especially favorable position to offer an acceptable program.

The collaborating industrial medical department, providing in-plant training, should be of sufficient size and scope to accommodate the requirements of the plant and shall be under full time medical direction. The medical director should derive his authority in the plant from the officer directly responsible for policy and operations. The plant should provide facilities and equipment and teaching material required for the training of a resident. Dressing and examination rooms, clinical and x-ray laboratories, wards and departments of physical medicine should be available. Physicians in training should become familiar with records pertaining to (1) individual medical services and examinations, (2) plant inspections and technical industrial hygiene studies and (3) absentee analysis and control measures. A well equipped laboratory and library of industrial hygiene should be readily accessible in the plant or through close affiliation with appropriate laboratories and libraries outside the plant. Monthly and annual summary reports should be prepared outlining the work of the department.

There is no certifying board in this field.

14. Ophthalmology

Acceptable residencies in this field should include active clinical experience in the diagnosis, therapy and surgery of ophthalmic disorders. There should be adequate experience with refraction, disorders of motility and binocular vision, perimetry, ophthalmoscopy, retinoscopy and the use of the slit lamp. There must be adequate equipment and facilities for such work. There should be an active consultation service provided to other departments of the hospital.

A systematic course of instruction should be offered with regular lectures and demonstrations in clinical and operative ophthalmology. Instruction in surgical technic should be sufficient to enable residents to undertake operative work on their own responsibility, especially toward the end of the training period.

See also the General Requirements for all residencies as given in Section I of these "Essentials."

Quantitative Requirements.—Ordinarily a minimum of 150 admissions and 1,500 outpatient visits a year is considered necessary for residency training in this specialty.

Applied Basic Science Instruction.—Histologic and pathologic material should be available for demonstration and individual study. Applied basic science work in anatomy, bacteriology, embryology, histology, pathology, pharmacology and physiology as relates to the eye should be included in the training program. Such work should be closely correlated with clinical experience. See Section I-9 of these "Essentials" for a discussion of applied basic medical science instruction.

Board Requirements.—The American Board of Ophthalmology requires candidates for the certification examination to have completed an internship of one year and a period of combined study, training and practice of not less than three years. A combined service in ophthalmology and otolaryngology should fulfill the requirements listed under each department except that five years of training and experience should constitute the minimum time required for certification in both fields.

15. Orthopedic Surgery

Surgical and orthopedic facilities must be satisfactory and clinical material sufficient to afford residents adequate experience in the correction of congenital and acquired deformities and in the treatment of fractures and other acute and chronic disorders which interfere with the proper function of the skeletal system and its associated structures. Residents should become thoroughly familiar with all methods of diagnosis and treatment, corrective exercises, physical medicine, operative procedures and the use of orthopedic appliances. Instruction in surgical technic should be sufficient to enable residents to undertake operative work on their own responsibility, especially toward the end of the residency program. Clinical instruction should include teaching rounds and departmental conferences.

Residencies may be organized in the fields of adult orthopedics, children's orthopedics, fractures or in combinations of these. As preliminary training the Council recommends one year of general surgery in addition to the internship.

See also the General Requirements for all residencies as given in Section I of these "Essentials."

Quantitative Requirements.—Both hospital and outpatient facilities are desirable, and institutions offering residency instruction should treat a minimum of 200 patients annually.

Applied Basic Science Instruction.—Anatomy, bacteriology, biochemistry, embryology, pathology and physiology are especially desirable and should be closely correlated with clinical experience. See Section I-9 of these "Essentials" for a discussion of applied basic medical science instruction.

Board Requirements.—The American Board of Orthopaedic Surgery requires candidates for the certification examination to have completed one year of internship, three years of concentrated training in orthopedic surgery and two years of subsequent practice in this special field. The training period should consist of balanced training in the fields of adult orthopedics, children's orthopedics, fractures and the applied basic sciences. Candidates may substitute a year of adult orthopedics and fractures for work in children's orthopedics. Candidates applying for certification after January 1, 1951, must also have completed an approved surgical residency of one year following the internship.

16. Otolaryngology

Residencies and fellowships in otolaryngology should aim to provide adequate clinical and operative experience. Essential equipment for diagnosis and surgery should be available, including an audiometer and other special apparatus depending on the scope of the service. The clinical material should be sufficient in variety and amount to provide adequate training in the various divisions of the service, which might advantageously include the field of bronchoscopy.

The training should include a systematic course of instruction with demonstrations on clinical and technical subjects pertaining to the various phases of otolaryngology. Instruction in surgical technic should be sufficient to enable residents to undertake operative work on their own responsibility, especially toward the end of the residency program.

See also the General Requirements for all residencies as given in Section I of these "Essentials."

Quantitative Requirements.—Ordinarily a residency program in otolaryngology requires clinical experience in a hospital which affords in the specialty a minimum of 400 admissions a year and at least 3,500 visits in the outpatient department.

Applied Basic Science Instruction.—There should be training in the applied anatomy of the ear, nose, throat, neck, chest and esophagus including the related nervous systems. Applied bacteriology, embryology, pathology, pharmacology and physiology should also be included and should be closely correlated with clinical experience. See Section I-9 of these "Essentials" for a discussion of applied basic medical science instruction.

Board Requirements.—The American Board of Otolaryngology requires candidates for the certifying examination to have an approved internship and three years of advanced preparation. A combined service in ophthalmology and otolaryngology should fulfill the requirements listed under each department except that five years of training and experience should constitute the minimum time required for certification in both fields.

17. Pathology

Residencies and fellowships, in contrast to the shorter courses for basic training in pathology, are ordinarily of one to three years' duration. The teaching material must be sufficient in kind and amount to afford residents adequate training in all divisions of the field including both gross and microscopic pathology. Systematic instruction should be carried out with the use of fresh material and collections of slides and museum specimens for comparative studies in histology and pathology. As the training continues an increasing amount of responsibility should be assigned to the residents in tissue diagnosis, in actual performance of postmortem examinations and in the preparation of pathologic reports and necropsy protocols. Further instruction should be obtained through active participation in clinical-pathologic conferences, staff meetings and joint conferences with other departments.

See also the General Requirements for all residencies as given in Section I of these "Essentials."

The relationship of the pathology service to residencies and fellowships in other fields is given in Section I-3.

Quantitative Requirements.—At least 100 necropsies a year should be performed in institutions offering residencies or fellowships in pathology.

Board Requirements.—The American Board of Pathology requires candidates for the certification examination to have completed, in addition to the internship, a period of study of at least three calendar years, including one year in the various phases of clinical pathology and not less than two years of training and experience in a department of pathologic anatomy. Such training may be combined or in sequence. An additional year of training or practice in pathology is likewise required.

18. Pediatrics

Clinical training should be obtained in general medical pediatrics, nutritional disorders, care of newborn infants, preventive pediatrics and outpatient clinics in the various departments of medical pediatrics. Correlative studies are recommended especially in contagious diseases, in clinics for well babies, the mentally deficient and in those with neurologic disorders or who present problems in behavior. In the wards and in the clinics the residents should be permitted to assume individual responsibility in diagnostic and therapeutic procedures and case management. They should actively participate in teaching rounds, clinical-pathologic conferences, departmental seminars and all other functions designed to improve the quality of the clinical and educational service. Although the training need not be continuous or in the same institution, it is desirable that the educational program be systematized in the form of residencies of one to three years' duration.

See also the General Requirements for all residencies as given in Section I of these "Essentials."

Quantitative Requirements.—To supply an adequate amount and variety of teaching material a department should provide a minimum of approximately 400 annual admissions in general medical pediatrics.

Applied Basic Science Instruction.—Sufficient time should be devoted to studies in applied basic sciences, especially in embryology, growth and development, nutrition, and other fields in physiology bearing upon pediatrics. This work should be closely correlated with clinical experience. See Section I-9 of these "Essentials" for a discussion of applied basic medical science instruction.

Board Requirements.—The American Board of Pediatrics requires candidates for the certification examination to have completed five years of training and practice after graduation from an approved medical school. The requirements include an approved internship of one year, a service of two years of acceptable training in pediatrics which may include a six months residency in contagious diseases and two additional years of specialized study or practice. Physicians who have met the requirements for certification in this field may seek further certification by this board in the special field of allergy, or certification in cardiovascular disease by the American Board of Internal Medicine.

Allergy. (See also Allergy under Internal Medicine.)—The objective of intensive training in allergy is to fit the physician for the highest type of practice, teaching and research in this specialty. An allergy residency should be at least one, though preferably two years of full time work. Residents in allergy should be given a thorough training in the fundamentals of human and animal sensitization through clinical study and laboratory experiments. There should be daily conferences or consultations with the staff. Reading of current articles and reviews of special topics should be assigned. Residents should be given responsibility for diagnosis and management of various diseases of allergy, for the teaching of interns, medical students and nurses as capability has been demonstrated. Problems in clinical or laboratory allergy should be utilized to develop an interest in research.

If the allergy service is a separate department, it should have interdepartmental associations so arranged as to give residents of the allergy unit continuing contact with the pediatric (or general medical) services through ward rounds, clinical-pathologic conferences, staff meetings, and so forth. The service should admit 200-300 ambulatory patients yearly, and have facilities for hospitalizing bed patients, in addition to cases seen in consultation with other services. It should have adequate laboratory facilities for those special chemical-immunologic, pathologic and bacteriologic procedures required in its field. The training of residents in allergy should be arranged to fit into the established programs of the American Boards of Pediatrics or Internal Medicine. Candidates for positions offering specialized training in allergy should previously have fulfilled the basic requirements of the parent board before undertaking study in the special field.

Certification in allergy is granted only to those who have previously fulfilled all the requirements for certification in pediatrics or internal medicine, including the examination.

19. Physical Medicine

The field of physical medicine includes all clinical and diagnostic uses of physical agents except those employed in radiology. Consequently, training and experience should be obtained in all divisions of this specialty including rehabilitation, sheltered work shop experience and occupational therapy. Mastery of the basic sciences and the technics used in physical therapy are essential, and experience in using these technics as well as supervising others in their use should be included in the experience of the resident. Orthopedic, psychiatric, tuberculous, general medical, general surgical and pediatric patients receiving physical therapy should be assigned to the department.

Adequate space and apparatus should be furnished in the department for all phases of the work The clinical material should be sufficient in kind and amount to enable the residents and fellows to observe and study all forms of treatment in physical medicine. Both inpatient and outpatient clinical material should be available.

As the resident progresses in this training program, a broader type of experience should be gained with increasing responsibilities in the functioning of the department, teaching various personnel, research, liaison with other departments and vocational counseling.

A minimum of three years of such training is generally considered necessary for a physician to become competent in the field of physical medicine. If a hospital is not equipped to offer this entire program, occupying three years, shorter training periods of one or two years may be organized or affiliations may be made with other units where the training and experience can be obtained on a full time assignment

20. Plastic Surgery

Adequate training and experience in plastic surgery should include experience in the various methods of plastic surgery of the scalp, face, jaw, neck, trunk and extremities. The resident should obtain experience in the various methods of skin, pedicle, flap, soft tissue and cartilage grafting. If the department of plastic surgery does not perform reconstruction operations on joints, tendons, nerves, perineum, extrophies or hypospadias it might be desirable to have the residents in training for plastic surgery witness such operations and study the progress of patients with such disorders.

Training in plastic surgery should be preceded by an approved internship and two years of residency training in general surgery, in which the resident becomes familiar with basic principles and procedures common to all surgery.

See also the General Requirements for all residencies as given in Section I of these "Essentials."

Quantitative Requirements.—A minimum of 150 individual plastic surgery patients cared for during the year is desirable to provide sufficient clinical material for the residents.

Applied Basic Science Instruction.—Applied basic science work in anatomy, bacteriology, biochemistry, pathology and physiology as related to plastic surgery should be closely correlated with clinical experience. See Section I-9 of these "Essentials" for a discussion of applied basic medical science instruction.

Board Requirements.—The American Board of Plastic Surgery requires candidates for the certification examination to have an approved internship of one year and at least six additional years of special training and practice as follows: two years of residency training in general surgery, two years of residency training in plastic surgery, and two additional years of practice or study in surgery a fair percentage of which shall be in plastic surgery.

21. Proctology (See Surgery.)

22. Psychiatry and Neurology

Residencies may be offered in either of these fields separately or in a combination of the two. In the training program, which may be of one to three years duration, depending upon the resources of the institution, emphasis should be placed on the educational features of the service, and the residents should receive regular instruction from members of the staff in general orientation in the specialty and diagnostic and therapeutic procedures and methods of clinical study, as well as in the organization of ward services. Administrative details and "paper work" should be kept within bounds so that the residents may employ their time in the study and treatment of neurologic and psychiatric disorders. Emphasis should be placed on the study of etiology, pathogenesis, symptomatology and course of the various diseases so that the residents may develop skill and accuracy in diagnosis, as well as mature judgment based on knowledge of the natural history of the diseases, and resourcefulness in therapy. There should be organized instruction in the fundamentals of psychopathology, psychotherapy and the dynamics of mental or emotional illness.

A rotating assignment in psychiatry is essential to give residents adequate experience in the various phases of in and outpatient psychiatry. Residents in psychiatry and neurology should have adequate contacts with other services, such as general medicine, pediatrics, tuberculosis services and so forth, so that they may become familiar with psychiatric and neurologic complications of general disease. Whenever possible neurologic residents should follow their patients through whatever neurosurgical operations are performed in the hospital. Teaching rounds, clinical and pathologic conferences and seminars are essential for clinical instructions in both fields.

The clinical material must be adequate in kind and amount. Too small a number of admissions prevents proper survey of the field of psychiatric and neurologic disorders. Numbers which are too large are incompatible with the adequate study of the patients admitted.

Some six months in specialized institutional psychiatry (feeble-minded, epileptic, penologic, drug and alcohol, and so forth) is of great value to the psychiatric residents as is six months of even half time duty in child psychiatry and experience in working with psychologists and psychiatric social workers.

It must be emphasized that residencies in psychiatric and neurologic hospitals are educational in character and that, of the full time psychiatric or neurologic staff of such hospitals, only those physicians who serve primarily on an educational basis come within the residency classification of the Council.

See also the General Requirements for all residencies as given in Section I of these "Essentials."

Quantitative Requirements.—The clinical material must be adequate in time and amount. Between 200 and 400 admissions a year per resident is considered desirable.

Applied Basic Science Instruction.—There should be instruction in the application to psychiatry and neurology of the basic sciences of anatomy, physiology and pathology. Such work should be closely correlated with clinical experience. See Section I-9 of these "Essentials" for a discussion of applied basic medical science instruction.

Board Requirements.—The American Board of Psychiatry and Neurology certifies physicians in either or both of these fields. Specialized training and experience of at least five years after the internship is essential to qualify for the certification examinations in neurology or in psychiatry. The requisite training consists of three full years of approved residency training after the general internship and two additional years of practice and experience in psychiatry or neurology or both. To qualify in both fields a minimum of seven years is required.

23. Pulmonary Diseases (See Internal Medicine.)

24. Radiology

Residencies and fellowships of three years duration should provide training in all divisions of the specialty—diagnostic roentgenology, therapeutic roentgenology and radium therapy. Without attempting to define a detailed plan of instruction it can be suggested that the first year be devoted principally to pathology, roentgenologic technic and a general orientation in the radiologic field. In the second and third years the clinical applications of radiology should be emphasized with at least six months assigned exclusively to radiotherapy. In view of the importance of pathology as a basis for radiologic diagnosis and therapy it is recommended that a minimum of six months be devoted to pathologic anatomy, particularly the study of gross pathology and tumors. Instruction in radiophysics and radiobiology may well run concurrently with the training in radium therapy and therapeutic roentgenology.

APPROVED EXAMINING BOARDS IN MEDICAL SPECIALTIES

An American board in a specialty is organized (*a*) to assist in improving the quality of graduate education in that field, (*b*) to establish minimum educational and training standards in the specialty, (*c*) to determine whether candidates have received adequate preparation, (*d*) to provide comprehensive examinations to determine the ability and fitness of such candidates and (*e*) to certify to the competence of those physicians who meet these requirements.

In 1933 the Council on Medical Education and Hospitals was authorized by the House of Delegates of the American Medical Association to formulate standards and to approve examining boards in the specialties which meet these standards. These standards were formulated and ratified by the House of Delegates in 1934. The most recent revision of these Essentials was approved Dec. 9, 1946.[1] The minimum requirements for certification were not increased, but various sections were rewritten for clarification. The "Essentials" outline the purpose and function of a specialty board, organization, definition of special fields, qualifications of candidates including professional education and special training, procedure to follow in the establishment of an acceptable board, mechanism for approval of a residency in a recognized specialty and withdrawal of approval to holders of certificates or from institutions offering residency training.

In 1933-1934 the Advisory Board for Medical Specialties was organized with representatives from each of the approved boards to "act in an advisory capacity to such organizations as may seek its advice concerning the coordination of the education and certification of medical specialists." The Council on Medical Education and Hospitals and the Advisory Board for Medical Specialties work in close collaboration through joint meetings and frequent conferences.

Prior to 1934 there were five examining boards in the medical specialties functioning, and since 1940 fifteen boards have been in operation. All these boards are fully approved by the Council. A key number has been designated for each board, such as A. B. 1, and the biographic records of physicians published in the American Medical Directory include by this means reference to those certified by these boards.

Each of the American boards has published a booklet containing a brief statement regarding its personnel, organization, purposes and qualifications for eligibility for certification. The current data pertaining to each board is reproduced in the following pages. There is also included the regulations of the Advisory Board for Medical Specialties.

In 1946 three boards certified candidates in subspecialties. The American Board of Internal Medicine certified in allergy, cardiovascular disease, gastroenterology and pulmonary diseases (formerly called tuberculosis). Similarly the American Board of Surgery certified specialists in proctology. The American Board of Pediatrics has developed procedures for certifying pediatricians in allergy and has certified five physicians to date. Regular board certification is a prerequisite for certification in the subspecialty. This function of these boards in internal medicine, surgery and pediatrics certifying specialists in the subspecialties is also approved by the Council. These subspecialties are fully recognized by the Council on Medical Education and Hospitals of the American Medical Association. As such they are appropriate fields in which to organize residency training when the facilities warrant. Approved training programs will be listed under these headings in the Council's official list of approved residencies whenever the subspecialty board so desires. The list of hospitals offering "Approved Residencies and Fellowships in the Specialties" also appears in this issue.

A list of the approved specialty boards and the number of certificates awarded prior to March 1, 1946 and the number certified to March 1, 1947 respectively appear in table 29. On March 1, 1946 there were 26,072 physicians certified by the fifteen boards, and in the year ended March 1, 1947, 2,404 were certified. Up to this date a total of 28,476 had been certified.

TABLE 29.—*Approved Examining Boards in Medical Specialties*

Key No.	Name of Board	Year of Incorporation	Total Certificates Awarded to March 1, 1946	Total Certificates Awarded to March 1, 1947
A.B. 1.	American Board of Pediatrics	1933	2,420	2,572
A.B. 2.	American Board of Psychiatry and Neurology	1934	1,993	2,438
A.B. 3.	American Board of Orthopaedic Surgery	1934	940	1,042
A.B. 4.	American Board of Dermatology and Syphilology	1932	753	844
A.B. 5.	American Board of Radiology	1934	2,198	2,366
A.B. 6.	American Board of Urology	1935	1,050	1,136
A.B. 7.	American Board of Obstetrics and Gynecology	1930	1,965	2,137
A.B. 8.	American Board of Internal Medicine	1936	3,906	4,449
A.B. 9.	American Board of Pathology	1936	1,240	1,359
A.B. 10.	American Board of Ophthalmology	1917	2,490	2,564
A.B. 11.	American Board of Otolaryngology	1924	3,886	3,958
A.B. 12.	American Board of Surgery	1937	2,620	2,904
A.B. 13.	American Board of Anesthesiology	1938	278	316
A.B. 14.	American Board of Plastic Surgery	1937	163	171
A.B. 15.	American Board of Neurological Surgery	1940	170	190
	Totals		26,072	28,476

Included in the 28,476 certified in major specialties are 882 who were also certified in subspecialties by the boards in internal medicine, pediatrics and surgery as follows:

Internal Medicine	
Allergy	95
Cardiovascular Disease	361
Gastroenterology	183
Pulmonary Diseases (formerly called "Tuberculosis")	163
Pediatrics	
Allergy	5
Surgery	
Proctology	75
Total	882

The greatest number in any one specialty were certified in internal medicine: 4,449 to March 1, 1947. Of this number 543 were certified in the past year. During the past year also 445 were certified by the board in psychiatry and neurology, bringing the total certified by this board to 2,438. Significant increases in the last year were also noted in surgery (284), obstetrics and gynecology (172), radiology (168) and pediatrics (152). Neurological surgery certified 20 and plastic surgery 8. The oldest board in existence, ophthalmology (organized in 1917) certified 74 last year, bringing the total certified to date to 2,564. Heretofore the greatest number certified in any one specialty was in otolaryngology. In this specialty 3,988 have received the board's certificate since its organization in 1924.

---

[1] J. A. M. A. **134:** 288 (May 17) 1947.

Table 30 gives the annual number of specialists certified by all boards for the past seven years and the accumulated totals. The largest number (2,404) obtained certificates in the period from March 1, 1946 to March 1, 1947. Of all those physicians now certified, 12,623 (44 per cent) received their specialty credentials in the past seven years.

Table 30.—*Annual Specialty Board Certifications Since 1940*

Year (Ended March)	Number of Boards in Existence	Number Certified That Year	Accumulated Totals
1940	14	....	15,851
1941	15	2,085	17,936
1942	15	1,758	19,694
1943	15	2,172	21,866
1944	15	1,578	23,444
1945	15	1,308	24,752
1946	15	1,320	26,072
1947	15	2,404	28,476

Ten boards recognize training with a qualified preceptor as a substitute for special clinical training. The policies of the boards toward the acceptance of such training are briefly outlined in table 31. The time credit allowed varies but in all instances is decided on an individual basis. The individual facilities and teacher qualifications of the preceptor must be approved by the respective board. This type of training is not accepted by five boards.

Table 31.—*Specialty Board Credit for Preceptorship Training*

		Preceptor Limitations			
	Credit Awarded	Any Certified Board Member	Other Than Certified Board Member	List of Preceptors Maintained	Maximum Clinical Training Credit
Anesthesiology	Yes	No[1]	Yes (rarely)[1]	No	2 years
Dermatology	Yes	No[1]	No	Yes	[3]
	No	...	...	...	....
	Yes	No[1]	No	No	No limit set
	Yes	Yes	Yes[1]	No	No limit set
	Yes	No[1]	Yes[1]	No	No limit set
	Yes	Yes	No	No	3 years
	Yes	Yes	Yes[1]	No	5 years [4]
	No	...	...	...	....
	No	...	...	...	....
	Yes	Yes	No	No	Full credit
	No	...	...	...	....
Radiology	No	...	...	...	....
Surgery	Yes	No[1]	No	No	2 years
Urology	Yes	Yes[2]	No	No	3 years

1. Facilities and teacher qualifications must be approved by board.
2. Board member must certify training facilities are adequate and must certify at end of training period that candidate has had adequate training.
3. Two years, half time, one half of each day being spent in an approved institution; or one year full time in the preceptor's office in localities where approved institutions are not available.
4. Six years required after July 1950.

Only four of the boards will give consideration to preceptor training carried out under a qualified specialist who is not himself certified by the appropriate board. One board maintains a list of preceptors.

The third edition of the "Directory of Medical Specialists," compiled by the Advisory Board for Medical Specialties, was published in 1946 and includes biographic data pertaining to the graduate educational background of each of the specialists certified by an American board. This directory lists 24,028 specialists certified prior to November 1945 and represents only those living at the time of publication but includes those retired from active practice.

AMERICAN BOARD OF ANESTHESIOLOGY

Ralph M. Tovell, President, Hartford, Conn.
E. A. Rovenstine, Vice President, New York.
Paul M. Wood, Secretary-Treasurer, 745 Fifth Avenue, New York.
John S. Lundy, Rochester, Minn.
Charles F. McCuskey, Los Angeles.
Henry S. Ruth, Philadelphia.
Meyer Saklad, Providence, R. I.
H. Boyd Stewart, Tulsa, Okla.
Ralph M. Waters, Madison, Wis.
T. Drysdale Buchanan, New York (Deceased)

HISTORY

The plan for this organization was devised . . . by a committee representing The American Society of Anesthetists, Inc., The American Society of Regional Anesthesia, Inc., and the Section on Surgery of The American Medical Association. These organizations adopted the tentative plans submitted, and the formation of The American Board of Anesthesiology, Inc., an affiliate of The American Board of Surgery, Inc., was completed on June 2, 1937. The Advisory Board for Medical Specialties, and the Council on Medical Education and Hospitals of the American Medical Association approved affiliation in 1938.

In 1941 the Advisory Board for Medical Specialties approved the establishment of The American Board of Anesthesiology, Inc., as a separate major board, with the unanimous consent of the participating societies and the surgical boards which are members of the Advisory Board.

Persons certified by this board (Diplomates) are designated "AB-13" in the directory and biographical departments of the American Medical Association, or "D.A.," Diplomate of The American Board of Anesthesiology, Inc.

PURPOSES

1. To establish criteria of fitness to be designated a specialist in the practice of anesthesiology.

2. To improve educational facilities and practice in medical schools and hospitals, furnish lists of these together with lists of individual instructors who give adequate instruction and training in anesthesiology.

3. To arrange, control, and conduct examinations to determine the qualifications, and grant a certificate to those who voluntarily apply and meet the required standards. Such certification will serve to provide the public and the professions with the opportunity to select the best available service (conferring of degrees is a prerogative of the universities, and the board of anesthesiology makes no attempt to grant degrees, regulate or control the practice of anesthesiology by license, or restriction).

VALUE OF CERTIFICATE

The organizations which participate in forming this board and sponsoring its activities as well as other societies or institutions, attach considerable importance to its certificate. The medical and lay public, as well as hospital directors, utilize the certification by this board in determining those who are well qualified as specialists in anesthesiology.

Although the directory of the American Medical Association indicates those practicing in the various specialties, the lists of holders of certification by specialty boards are available in the form of the Directory of Medical Specialists.

The American Board of Anesthesiology is willing to cooperate with institutions and individuals in preparing plans for instruction in anesthesiology and in offering suggestions for the organization of new departments in the specialty.

QUALIFICATIONS FOR ELIGIBILITY TO CERTIFICATION

A. *General.*—1. An applicant's moral and ethical standing in the profession must be satisfactory to the entire board. The board must be assured that the applicant is engaged in the practice of anesthesiology as a specialty and that he intends to continue to be so engaged.

2. Membership is required in the American Medical Association or membership in such other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association. Membership in other societies shall not be required.

3. Practice must have been *limited* to anesthesiology for five calendar years of which at least two *must* have been devoted to special training.

4. In exceptional instances the board may, in its discretion, accept for examination, candidates who have met all the preliminary requirements, and have clearly demonstrated their identity as anesthetists over a period of years, but whose formal training does not comply with the full requirements.

B. *Professional Standing.*—1. An applicant must be a graduate of an approved medical school in the United States or Canada recognized by the Council on Medical Education and Hospitals of the American Medical Association, or must be a diplomate of the National Board of Medical Examiners.

2. Satisfactory evidence must be supplied of completion of an internship of not less than one year in a hospital approved by the same council, or its equivalent in the opinion of the board.

3. An applicant must establish in a manner satisfactory to the board of anesthesiology: that he is a physician duly licensed by law to practice medicine; that he is of high ethical and professional standing; and that he has received adequate training in anesthesiology.

C. *Special Training and Practice.*—1. Before certification the candidate must have had an active experience limited to anesthesiology of not less than five (5) calendar years (including period of training).

2. The board requires the inclusion of at least two years of carefully supervised instruction in the clinical phases of anesthesiology in hospital clinics, dispensaries, and diagnostic laboratories recognized by the Council on Medical Education and Hospitals of the American Medical Association as competent in the teaching and practice of anesthesiology. In addition, instruction in anatomy, physiology, pharmacology, biochemistry and other basic sciences, which are necessary to the proper understanding of the problems involved in the specialty of anesthesiology is required.

EXAMINATIONS

The qualifying examinations will be divided into Part I, written, Part II, oral, and Part III, practical.

PART I

1. An applicant to be eligible for Part I, must meet all training requirements, and his credentials must be approved by the board.

2. Part I may be given simultaneously in several places, which the board may deem suitable for the purpose.[1]

PART II

1. In order to be eligible for Part II, a candidate must have successfully passed Part I.

2. It is probable that Part II examinations will be held near the time and at the place of the annual Convention of the American Medical Association. Later, however, as the demand grows, it may be necessary to establish subsidiary centers where this part may be held.[2]

PART III

1. The examiners will observe the work of the candidates in their own or similar operating room surroundings, their relations to other staff members, and investigate their professional standing.

CONDUCT OF EXAMINATION

Carefully conducted and thorough examinations will be required of candidates. The aim will be to avoid unduly exacting standards above present facilities for study and practice in anesthesiology, and on the other hand, to prevent laxity, which would nullify the main purpose of the certification. Thus the type of examination will depend upon a careful review of the work done, years of practice, special courses of study, and professional standing, of the applicant.

Written examinations will cover such topics as anatomy, biochemistry, physiology, pharmacology, pathology, physical diagnosis, therapeutics, and clinical practice in relation to anesthesiology.

Oral examinations will cover topics in the above list, especially as to their clinical application.

Practical demonstrations will be required of the management of the candidate's clinical practice in his local surroundings. This may include inspection of clinical records, records of departmental activities, library facilities, available apparatus and demonstrations of application of anesthetic agents, methods and all techniques included in anesthesiology.

GRADES

A candidate must receive a passing average for each Part to be entitled to certification. No candidate shall pass a Part who does not receive a grade of 60 per cent or more in each subject of such Part. An average grade of 75 per cent shall be required for passing.

A candidate who fails in his examination in Parts I, II or III may be permitted reexamination at yearly intervals for two (2) consecutive examinations in that part without further payment of fee. The board may, however, for sufficient reasons, deny a candidate the privilege of reexamination.

Applicants who fail to exercise the examination privilege within three (3) years of the date of filing the application and of becoming eligible for examination, are required to file a new application and pay a new application fee.

FEE

The fee shall be $75 (after Jan. 1, 1948—$100). At least $25 shall be paid on filing the application (of which sum $15 will be returned if the candidate is not accepted for examination) and the remainder shall be paid before taking the examinations.

This board is a nonprofit organization. All fees are to be used to extend the existing facilities for training in anesthesiology, after deducting necessary expenses for maintenance of the office, and the conducting of examinations. The board reserves the right to increase the fee when found necessary.

REVOCATION OF CERTIFICATE

All certificates issued by the board shall be subject to revocation by the board at any time, in case it shall determine in its sole judgment that a physician who has received a certificate, either was not properly qualified to receive it or has become disqualified since its receipt.

ADDITIONAL INFORMATION

Every candidate applying for certification must personally appear before the board before being certified.

Application must be made on special blanks which may be procured from the secretary of the American Board of Anesthesiology. They must be completely and accurately filled out, accompanied by the other required credentials and filed with the secretary at least 180 days prior to the date of examination. Before filing, applicants must have completed one year of approved anesthesia residency.

The secretary cannot make any eligibility rulings. These are made only by the entire board on recommendation of the appropriate committees after reviewing the candidate's formal application. Applications cannot be considered for classification and action by these committees unless accompanied by an application fee of $25, $10 of which is not returnable.

Application blanks contain the following statement:

"I hereby make application to The American Board of Anesthesiology, Inc., for the issuance to me of a Certificate of Qualification as a specialist in anesthesiology and for examination relative thereto, all in accordance with and subject to its rules and regulations, and enclose fee of seventy-five dollars ($75).[3] I agree to disqualification from examination or from the issuance of a Certificate of Qualification or to surrender of such certificate as directed by the board, in the event that any of the statements hereinafter made by me are false or in the event that any of the rules governing such examinations are violated by me or in the event that I did not comply with or shall violate any of the provisions of the Certificate of Incorporation or Constitution and By-Laws[4] of The American Board of Anesthesiology, Inc., or both, as then constituted. I agree to hold the American Board of Anesthesiology, Inc., its members, examiners, officers and agents free from any damage or complaint by reason of any action they or any of them, may take in connection with this application, such examinations, the grade or grades given with respect to any examination, or the failure of said board or corporation to issue to me such Certificate of Qualification."

Proper forms for making application and other information may be obtained by writing to the Secretary.

---

[1] Written examinations are held on the third Friday of January annually.

[2] Oral examinations are held during the third week of October annually.

[3] This may be paid as follows: $25 with application ($10 registration fee not returnable) and $50 before examination.

[4] Ignorance of the provisions of the Certificate of Incorporation and of the Constitution and By-Laws is not considered by the board to be a valid excuse for violations, as failure to maintain 100 per cent limitation of practice to anesthesiology, fee-splitting, etc.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY

Francis E. Senear, President, Chicago.
J. Gardner Hopkins, Vice President, New York.
George M. Lewis, Secretary-Treasurer, 66 East 66th Street, New York.
Frank E. Cormia, Assistant Secretary, New York.
Anthony C. Cipollaro, New York.
Henry E. Michelson, Minneapolis.
Hiram E. Miller, San Francisco.
Paul A. O'Leary, Rochester, Minn.
Bedford Shelmire, Dallas, Texas.
Fred D. Weidman, Philadelphia.

ORGANIZATION

At the 1931 meeting of the American Dermatological Association, a committee was appointed to determine the advisability of forming an American board for the certification of competent practitioners in this specialty. . . . A similar committee was appointed by the Section on Dermatology and Syphilology of the American Medical Association at its meeting in the same year. A favorable report was rendered by each committee at the 1932 meetings of these organizations.

The American Dermatological Association voted to accept the report of this committee, and the president appointed the following four members to represent the Association on the newly formed American Board of Dermatology and Syphilology:

Jay F. Schamberg, Philadelphia.
Howard Fox, New York.
Harold N. Cole, Cleveland.
Arthur W. Stillians, Chicago.

The Section on Dermatology and Syphilology of the American Medical Association also accepted the report of its committee and the chairman appointed the following members to serve as its representatives:

Howard Morrow, San Francisco.
William H. Mook, St. Louis.
George M. MacKee, New York.
C. Guy Lane, Boston.

The first meeting of the board was held in New Orleans on May 11, 1932, at which time officers were elected. At another meeting held on November 11, 1932, in Philadelphia, the organization was completed and resolutions were adopted concerning the proper procedure to be followed by the board. On November 29, 1932, the board was incorporated under the laws of the State of Delaware.

In 1937 the American Academy of Dermatology and Syphilology was formed, and in November, 1939, a plan was finally approved whereby the board would be composed of three representatives from each national dermatological society, viz., the American Dermatological Association, the Section on Dermatology and Syphilology of the American Medical Association, and the American Academy of Dermatology and Syphilology.

These representatives are the *members* of the board. A physician who fulfills the requirements of the board and is awarded a certificate is known as a *diplomate*.

PURPOSES

The board has been established primarily to determine the competence of physicians who specialize in dermatology and syphilology. It will therefore establish minimum standards of education and training, examine applicants and certify properly qualified specialists in this field, prepare lists of those qualified and arrange for the publication of such lists. Because of its interest also in the fulfillment of these standards, it will attempt to stimulate the development of adequate training facilities, investigate institutions and individuals planning to train specialists, and lend its aid to the approval of those institutions and individuals offering adequate training in the specialty. The board, in addition, will always be glad to advise physicians desiring to enter this special field of medicine.

REQUIREMENTS FOR ELIGIBILITY FOR EXAMINATION

I. General Requirements

1. High ethical and professional standing.
2. Graduation from a medical school recognized by the Council on Medical Education and Hospitals of the American Medical Association.
3. Satisfactory completion of an internship of not less than one year in a hospital approved by the same Council, or its equivalent in the opinion of the board.
4. A license to practice medicine.
5. Membership in the American Medical Association or membership in a similar society recognized as having the same purpose as the American Medical Association.
6. Citizenship in the United States or citizenship—meaning native citizens—in Canada or Cuba.

II. Special Requirements

Applicants for certification of the board are classed in two groups as follows:

Group A consists of physicians who have limited their practice mainly to dermatology and syphilology for ten or more years, including a period of training satisfactory to the board.

Group B consists of physicians who have completed an approved three-year period of training.

In accordance with the program recommended to the various specialty boards by the Advisory Board for Medical Specialties the following minimum requirements of special training for admission to examination have been established:

A period of study, after the internship, of not less than three years. This training may be obtained as resident, fellow or graduate student in clinics, dispensaries, hospitals or laboratories recognized by the Council on Medical Education and Hospitals of the American Medical Association and approved by the American Board of Dermatology and Syphilology as competent to provide a satisfactory training in dermatology and syphilology. This period of specialized training shall include:

(*a*) Graduate training in the basic medical sciences which are necessary for the proper understanding and treatment of the diseases involved in this specialty.

Instruction in the following fundamental subjects as related to the skin is deemed advisable by the board: embryology, histology, chemistry, physiology, bacteriology, mycology, parasitology, pathology, immunology, serology, pharmacology and materia medica and physics of physical therapy.

(*b*) Carefully supervised clinical and laboratory experience in the specialty.

(*c*) Annual examinations in the clinical, laboratory and public health aspects of dermatology and syphilology.

PRECEPTORSHIP TRAINING

Candidates may spend one year of their training in the office of a diplomate of the board, who has also been approved as a preceptor by the board. The office training may be divided over two years, in which case one-half day is spent in the office of the preceptor and the other half day in an approved institution. If no approved institution is available, only one year of training may be satisfied by working under the preceptor and two years of work in an approved institution will be necessary to fulfill the requirements. Preceptorship training may be taken during any of the years of training. Time spent with an instructor who has not been approved by the board may count only as experience and not as training.

The board assumes the responsibility of determining the standards of knowledge to be acquired, but on the candidate rests the responsibility of acquiring the knowledge to fulfill these standards.

APPLICATION AND FEE

In order that the Committee on Requirements may appraise carefully the qualifications of candidates, application must be made on a special blank, which may be obtained from the secretary. No application will be considered unless made on the regular application blank. Applications should be filed early in order to obtain full advantage of the sets of histopathological slides which are available through the Army Medical Museum in Washington. The completed application blank should be sent, at least two months before the date of examination, to the secretary of the board together with the required reprints, photographs, and a *registration* fee of $25 which will not be refunded under any circumstances. No application will be considered until this fee is received. An *examination* fee of $50 is payable when the candidate is notified that his application is acceptable to the board. The fee of $75 has been carefully computed and is used entirely for administrative purposes. Examiners for the board do not receive any compensation except for actual expenses connected with holding the examinations.

Make checks payable to American Board of Dermatology and Syphilology, Inc.

EXAMINATIONS

Applicants classified in Group B will be required to pass a written examination. This written examination on clinical, basic science and laboratory subjects will be held simultaneously at stated intervals in different parts of the country, approximately two months before the oral examination.

Applicants classified in either Group A or in Group B will be required to pass an oral, clinical and laboratory examination. This examination will be conducted in a clinic or hospital ward where individual cases will be discussed with each candidate, as well as various subjects related to the skin such as histopathology, mycology, allergy, and physics or physical therapy. The board reserves the right to add to this list other subjects within the field of dermatology and syphilology.

A candidate for a certificate may take both the *written* and *oral* examinations at the next regular examination of the board after he has completed three full years of training in the specialty; this provision does not affect the regulations about the issuance of the certificate.

Examinations are designed to test the candidate's fitness to practice dermatology and syphilology as a specialty. The board will try especially to ascertain the breadth of his clinical experience, his knowledge of recent literature of dermatology and syphilology, and his general qualifications as a specialist in this branch of medicine.

Whenever an applicant fails to pass the examination, the board, if requested, will make suggestions as to suitable courses of instruction for the purpose of overcoming deficiencies in the applicant's knowledge of this specialty.

Except in special circumstances, applicants shall take the examination within the year following the filing of application and the deposit of the fee.

The oral examination may be held near the time and place of the annual meeting of the American Academy of Dermatology and Syphilology. This examination will be held only at the time of regular meetings of the board.

REEXAMINATIONS

If the candidate fails or is conditioned in an examination he will be admitted to a second examination after one year, and must give sixty days' notice of his intention to appear for reexamination. If a candidate who has failed or has been conditioned does not appear for reexamination before the expiration of three years, he will be required to make a new application and pay an additional fee of $50 before reexamination.

A candidate who has failed twice must file a new application and pay an additional fee of $50.

CERTIFICATES

A certificate will not be issued until the candidate has completed at least five years of dermatologic training and experience. The granting of this certificate by the board indicates that the holder of the certificate has had adequate training in dermatology and syphilology and has successfully fulfilled the requirements of the board.

Medical schools, hospitals, physicians, the Army, the Navy, the Public Health Service, and various governmental and philanthropic agencies, as well as the lay public, all utilize the certificate from this board as a proof of adequate preparation in the field of dermatology and syphilology and of fitness of candidates for positions under their control. For this purpose, lists of those holding certificates from the board are available for inspection and are published from time to time in the Directory of Medical Specialists. Diplomates are identified in the Directory of the American Medical Association.

A certificate granted by this board does not of itself confer or purport to confer any degree or legal qualifications, privileges, or license to practice dermatology or syphilology. The board does not intend to limit or interfere with the professional activity of any duly licensed physician. Its aim is to improve the standards of practice of dermatology and syphilology by encouraging improvement in the opportunities for and quality of training for specialists in this field of medicine, and to certify, as specialists, those who voluntarily comply with the requirements of the board.

Certificates will be issued only to physicians in the United States and its possessions, in Canada, and in Cuba.

REVOCATION OF CERTIFICATES

The certificates issued by the board are issued subject to the provisions of the certificate of incorporation and of the by-laws, and each certificate is subject to revocation in the event that: (a) the issuance of such certificate or its receipt by the physician so certified shall have been contrary to any of the provisions of the certificate of incorporation or by-laws; or (b) the physician so certified shall not have been eligible to receive such certificate, irrespective of whether or not the facts constituting him so ineligible were known to or could have been ascertained by the directors of the board at the time of the issuance of such certificate; or (c) the physician so certified shall have made any misstatement of fact in his application for such certificate or in any other statement or representation to the board or its representatives; or (d) the physician so certified shall have been convicted by a court of competent jurisdiction of a felony or of any misdemeanor involving, in the opinion of the Board of Directors, moral turpitude in connection with his practice of medicine; or (e) the physician so certified shall have had his license to practice medicine revoked or shall have been disciplined or censured as a physician by any court or other body having proper jurisdiction and authority.

CREDIT FOR MILITARY SERVICE

In view of the variability of dermatologic work and the differing conditions under which it was carried on by commissioned medical officers of the Army, Navy and Public Health Service, the board is unable to issue specifications for eligibility for examination to cover every situation that has arisen in the experience of every candidate, but the following general statements can be made.

1. Full credit will be given for dermatologic training in approved institutions, which preceded the military service.
2. Full time dermatologic military service may be credited, at the discretion of the board, for part or in some cases all of two years of the three required years of *training*. At least one year of the three years' required training including instruction in the fundamental subjects deemed essential for an adequate dermatologic education must be spent in one of the institutions approved for a three year training program by the board and by the Council on Medical Education and Hospitals of the American Medical Association.
3. In any event, the board strongly urges that the candidate supplement his military experiences by a further period of systematic and supervised dermatologic training before the examination.
4. A credit of one year as *experience* has already been voted by the board for one year of any military service. Thus a medical officer who passes the examination at the end of three years of training will receive his certificate one year later instead of at the completion of a total of five years' training and experience. Dermatologic work while in the armed forces not credited as training, may satisfy part or all of the remaining year of required dermatologic experience.
5. For commissioned officers the total fee will be $50 instead of $75. Of this, $25 must accompany the application. The examination fee of $25 is payable when the candidate is notified that his application has been approved by the board. These fees are not returnable.

PUBLICATIONS OF THE BOARD

1. Booklet of Information.
2. Opportunities for Graduate and Postgraduate Students in Dermatology and Syphilology, containing a list of loci where instruction may be obtained, and details about these places.
3. The names of all the diplomates are included in the third edition of the Directory of Medical Specialists published in 1946, by the A. N. Marquis Company, 210 East Ohio Street, Chicago 11, Illinois.
4. Syllabus of Graduate Training:

(*a*) To inform the student physician, intending to specialize, of the field to be covered in his preparation and the methods by which his preparation can be accomplished.

(*b*) To aid the medical schools and the dermatologic departments of medical schools and hospitals by outlining the scope of teaching deemed advisable for specialization in dermatology and syphilology.

INSTRUCTIONS TO APPLICANTS

Fill out application blank in detail.

Enclose fee of $25. (Make check payable to the American Board of Dermatology and Syphilology, Inc.)

Include *autographed* photographs as directed on application blank.

Enclose reprint of each published paper, if possible.

Send completed applications and above items to the secretary.

Please indicate under No. 13 on the application blank as complete data as possible about your training in dermatology and syphilis. Indicate the month and year, if possible, or at least the number of months of the various parts of your training and also whether full time or part time. If part time, indicate whether one-half day, six days a week, or three days a week, etc. If dispensary service is considered as part of your training, please indicate details here as well as under No. 14.

In No. 16 indicate clearly when you began to limit your practice to dermatology and syphilis.

If your training and your practice overlap, please explain under No. 19.

Further information may be obtained from the secretary.

AMERICAN BOARD OF INTERNAL MEDICINE

James J. Waring, Chairman, Denver.
Hugh J. Morgan, Secretary-Treasurer, Vanderbilt University Hospital, Nashville, Tenn.
William A. Werrell, Assistant Secretary-Treasurer, 1 West Main Street, Madison 3, Wis.
William S. McCann, Rochester, N. Y.
Marion A. Blankenhorn, Cincinnati.
LeRoy H. Briggs, San Francisco.
Alexander M. Burgess, Providence, R. I.
William B. Porter, Richmond, Va.
Burrell O. Raulston; Los Angeles.
Truman G. Schnabel, Philadelphia.
Roy W. Scott, Cleveland.
Virgil P. W. Sydenstricker, Augusta, Ga.
Cecil J. Watson, Minneapolis.

ORGANIZATION

The American Board of Internal Medicine was established in 1936 by joint action of the Section on the Practice of Medicine of the Americal Medical Association and the Board of Regents of the American College of Physicians. It is a nonprofit organization incorporated for the benefit of physicians who because of their training and experience desire to be certified formally as specialists in internal medicine by a representative group of their colleagues.

The board consists of twelve members; seven are nominated by the American College of Physicians and five by the Section on Internal Medicine (formerly the Practice of Medicine) of the American Medical Association. Each member of the board serves for a term of three years but may be nominated and elected for a second term of three years. However, no member may serve for longer than two successive terms. The service is voluntary and members of the board do not receive compensation beyond the actual expenses incurred at the oral examinations or at special meetings.

RESPONSIBILITIES

The major object of the board is to pass judgment on the competence of internists who desire certification—not to determine who shall or shall not practice internal medicine as a specialty.

The American Board of Internal Medicine is not concerned with any mechanism which gains special privileges or specific recognition for those physicians who have been certified in internal medicine. It has never been the intent of the board to define requirements for membership on the staff of hospitals.

This board endorses completely the stand of the American Board of Surgery which "specifically disclaims interest in or recognition of differential emoluments that may be based on certification."

REQUIREMENTS FOR ADMISSION TO EXAMINATION AND CERTIFICATION

Each applicant for certification by this board must satisfy the qualifications listed below under, I General Qualifications A, B, C, D and II Professional Qualifications A, B, C, D. For exceptions to the requirements see C and D under Professional Qualifications.

I. General Qualifications

A. All candidates must be citizens of the United States or Canada.

B. All candidates must present evidence of satisfactory moral and ethical standing in the medical profession.

C. All candidates must be active members in good standing in their county and state medical societies in their state of legal residence. (This ruling shall not apply to commissioned officers of the United States regular Army or Navy while serving outside the territorial limits of the United States.)

D. Canadian citizens applying for admission to examination must be active members of the Canadian Medical Association.

II. Professional Qualifications

A. Graduation from a medical school approved by the Council on Medical Education and Hospitals of the American Medical Association at the date of graduation.

B. Satisfactory completion of an approved internship of not less than twelve months.[1]

C. Approved residency or fellowship training in internal medicine according to the following plan (Plan A) or one of the alternate plans described under paragraph D below.

Plan A: A residency or fellowship in internal medicine for a period of not less than three years in a hospital or other institution approved by the Council on Medical Education and Hospitals of the American Medical Association for residency or fellowship in internal medicine. In addition, two years of practice of clinical internal medicine will be required. The board will accept the following equivalents as satisfying one year only of the three years of residency or fellowship to which this paragraph refers.

1. A second year (or a part thereof) of approved internship in a hospital approved for resident training in internal medicine if limited to the medical service (or medical specialties noted under 2) for one year and if recognized as being the equivalent of an assistant residency by the medical director of the hospital and the chief of the medical service.

2. One year of approved residency in one of the medical specialties: allergy, cardiovascular disease, gastroenterology, hematology, pulmonary diseases, neurology, pediatrics and psychiatry.

3. One year of approved residency in pathology.

4. One year as a graduate student or as an instructor in an approved medical school on a full time basis in bacteriology, biochemistry, pathology, pharmacology, physiology or internal medicine.

5. An advanced degree in the fundamental sciences.

Note: Graduate training credit for the time involved will be allowed veterans and other candidates who take and satisfactorily complete postgraduate courses in internal medicine or the basic medical sciences provided by accredited medical schools. This ruling shall not apply to courses of less than three months' or more than twelve months' duration. A certificate of creditable performance, based in part at least, on a formal examination on completion of the course, will be required.

D. *Alternate Training Plans:* The board firmly believes that the plan of intensive training prescribed above offers the best opportunity for a young physician to prepare himself to meet his responsibilities as a specialist in internal medicine. It is recognized, however, that capable individuals may accomplish the same result in a longer period of time during which the training is less intensive. The board realizes that a number of medical graduates cannot follow the shorter and more desirable plan either because suitable residencies are not available, or in some instances because of personal and economic reasons. Accordingly the board has modified its previous regulations governing eligibility for admission to examination. In doing so the board has not modified its standards of examination. It has liberalized its eligibility requirements for admission to examination by accepting half time formal training, and the practice of internal medicine under favorable circumstances as to professional and hospital contacts, in lieu of part of the full-time requirements. It is hoped that by this means exceptional individuals may acquire a knowledge of medicine and experience in its application sufficient to qualify for certification.

The program already described (Plan A), which consists of three years of formal training in an approved residency or its equivalent, following internship, and two additional years in the practice of internal medicine, is recommended by the board. Variations in this program are now made subject to the following regulations.

1. In all instances, one year of approved internship and one year of approved residency will be required, except as indicated under Plan "G." The graduate training credit of one year heretofore granted as a result of active duty as a commissioned officer in the Armed Forces during the period beginning Dec. 7, 1941, and ending Jan. 1, 1947 may not be applied in satisfaction of the one year of approved residency referred to in Plans D, E, F, unless the candidate's assignment is considered by the board to have been equivalent to an approved residency.

2. Following one year of internship and *two years* of approved residency,[2] the remaining requirements may be satisfied by:

Plan B that is, by two years of half time formal training followed by two years of practice limited to internal medicine, or by

Plan C that is, by five years of practice limited to internal medicine.

3. Following one year of internship and *one* year of approved residency, the remaining requirements may be satisfied by:

The data pertaining to the American Board of Internal Medicine represents an advance copy of the revision of the regulations of the board which was sent for publication in this issue prior to its final approval by the board. Any changes in the regulations as finally adopted will be of a minor nature.

[1] During the period in which the 9-9-9 program was in effect an approved internship of nine months will satisfy the requirements of twelve months. A residency of nine months is considered as nine months only.

[2] For the second year of approved residency one of the equivalents described under C may be substituted.

Plan D that is, by four years of half time formal training followed by two years of practice limited to internal medicine, or by

Plan E [3] that is, by two years of half time formal training followed by five years of practice limited to internal medicine, or by,

Plan F that is, by eight years of practice limited to internal medicine.

4. In every instance at least two years of practice in internal medicine must be included, but in instances in which four years of practice are substituted for one year of residency, only one additional year of practice will be required. When more than eight years of practice are substituted for two years of residency an additional year of practice will not be required.

5. Physicians who have practiced internal medicine for twelve years following an approved internship may qualify for the examinations without further training. (Plan G.)

Half time formal training under expanded plans B, D and E is defined as follows:

1. Half time as an instructor in clinical medicine in a recognized medical school in the United States or Canada.
2. Half time in a research fellowship sponsored by a recognized medical school in the United States or Canada.
3. Half time as a graduate student in an approved graduate medical school in the United States or Canada.

E. *Practice Requirements:* A period of not less than two years of practice in the general field of clinical internal medicine or in the more specialized branches of medicine. (See exceptions—paragraph 4.) This requirement may be satisfied by independent practice or in association with a recognized internist.
